INDEX

NAME INDEX

Aavakivi (R.), [Prof. H. Perlitz and], Atomic Parameters of γ-Silver-Cadmium, 708
Abbie (Dr. A. A.), The Ancestors of the Eutheria, 523
Abderhalden (Prof. E.), elected an honorary member of the Société Philomathique of Paris, 110
Abercrombie (M.), Evocation in the Chick, 1091
Adams (Dr. T.), Town Planning and Urban Concentration, 603
Adamson (A. M.), Fauna of the Marquesas Islands, 1007
Adarkar (B. P.), If War Comes (an essay on India's Military Problems), (*Review*), 371
Addison (Dr. C. C.), 'Breaks' in Interfacial Tension Curves, 249; Interfacial Activity of Short-chain Isomers, 783
Adrian (Prof. E. D.), appointed a member of the Medical Research Council, 905
Agar (H.), appointed tutor in obstetrics and gynæcology in Leeds University, 47
Aharoni (Dr. J.), A New Method of Determining e/m for Medium High Velocities, 203
Ahmad (Dr. Nazir), Transplants of Sea-Island Cotton, 785
Aiyar (Prof. R. G.), Salmacis (The Indian Sea-Urchin), (*Review*), 363
Albert (Prof. A. L.), Fundamental Electronics and Vacuum Tubes (*Review*), 401
Albrecht (G.), and R. B. Corey, Crystal Structure of Glycine, 40
Allard (W.), The Hydrology of the Upper White Nile (*Review*), 495
Allchin (J. P.), [Dr. J. Newton Friend and], Colour of Celestine, 633
Allcock (H. J.), and J. R. Jones, The Nomogram: the Theory and Practical Construction of Computation Charts. Second edition (*Review*), 369
Allee (Prof. W. C.), The Social Life of Animals (*Review*), 5; [Prof. O. Park, Prof. V. E. Shelford and], A Laboratory Introduction to Animal Ecology and Taxonomy (*Review*), 583
Allen (Dr. J. F.), and Dr. J. Reekie, Forces Associated with Heat Flow in Helium II, 475
Allen (Prof. S. W.), An Introduction to American Forestry (*Review*), 614
Allen (W. D.), and C. Hurst, Scattering of D—D Neutrons, 509
de Allende (T. Lopez Colombo), Female Reproductive Organs of the Toad, 253
Allison (F. E.), C. A. Ludwig, S. R. Hoover and F. W. Minor, Legume Nodule Metabolism and Nitrogen Fixation, 711
Ambler (F. W.) [E. P. Wilson and], Revision Notes in Inorganic Chemistry: to Higher School Certificate (*Review*), 1079
Amulree (Lord), The Museum as an Aid to the Encouragement of Arts, Manufactures and Commerce, 124
Anderson (M.), Coal Utilization by Electricity, 505
Anderson (Prof. W. B.), Physics for Technical Students: Sound, Electricity and Magnetism, Light. Third edition (*Review*), 373
Andrade (Prof. E. N. da C.), and C. Dodd, Effect of an Electric Field on the Viscosity of Liquids, 117
Andrew (G.), appointed Government geologist in the Anglo-Egyptian Sudan, 1010
Angell (Prof. F.), [death], 933
Antevs (E.), elected a corresponding member of the American Geographical Society, 199
Appel (H. P.), [R. Furth, K. Sitte and], Determination of Stellar Diameters by Interferometer, 40
Appell (P.), Analyse mathématique, cinquième édition. Tome 2 (*Review*), 369
Appleton (Prof. E. V.), Characteristic Variation of Region F_2 Ionization throughout the Year, 151
Appleyard (Dr. E. T. S.), [obituary article], 14
Aravamuthan (J. G.), India and Crete, 1095
Archenhold (H. G.), Sunspots and Magnetic Disturbances, 985
Arhimo (Dr. A. A.), [Prof. A. I. Virtanen and], Oxalo-acetic Acid in the Leguminous Plants, 36; [Prof. A. I. Virtanen, Dr. H. Suomalainen and], Estimation and Occurrence of Keto-Acids in Green Plants, 597
Armitage (E.), Higher School Certificate Practical Physics (*Review*), 743
Armstrong (Dr. E. F.), The Leader to Perfect Health (*Review*), 264
Arnot (Dr. F. L.), resignation of lectureship in St. Andrews University; appointed a lecturer in Sydney University, 127
Arps (Prof. G. F.), [death], 624
Asami (Prof. Yoshihiro) and Prof. Takeo Hori, Spectrum of the Torch Discharge, 981
Ashbridge (Sir Noel), Progress Made in Broadcasting and Television, 322
Ashby (Prof. E.), Correlation between Seed Weight and 'Adult' Weight in Tomatoes, 712
Ashworth (Dr. J. R.), Ferromagnetism: the Development of a General Equation to Magnetism (*Review*), 399
Assémat (Dr. A.), Dust and Disease, 662
Astrup (Dr. T.), Autocatalysis and Blood Coagulation, 76
Atkin (W. R.), appointed honorary research assistant of the Procter International Research Laboratory, 938
Atkinson (Dr. G. H.), [Dr. G. W. Brindley and], Effect of Temperature on the Intensity of X-Ray Reflections from Copper, 477
Atkinson (W. T.), awarded a scholarship of the North-East Coast Institution of Engineers and Shipbuilders, 665
Auber (Dr. L.), The Colour-producing Structure in the 'Dominant Grey' Budgerigar, 157
Auerbach (C.), [Prof. F. A. E. Crew and], Genetics of the Rex Mouse, 557
Auger (Dr. P.), Scientific and Technical Literature and Information, 1089
Avery (A. G.), [A. F. Blakeslee and], Fifteen Years' Research on Datura, 253
Avery (J. H.), [W. F. F. Shearcroft and], Practical Physics (*Review*), 743
Avery (P.), [T. H. Goodspeed and], Trisomic Nicotiana, 1095
Awbery (J. H.), The Teaching of Mechanics, 792
Axelrod (A. E.), H. A. Sober and Prof. C. A. Elvehjem. Reduction of the *d*-Amino-Acid Oxidase Content of Rat Tissues in Riboflavin Deficiency, 670
Aykroyd (Miss Olive E.), [Prof. J. B. Gatenby and], Cytology of the Human Uterine Gland Cell, 331

Aynard (Rose), [Prof. J. Cabannes and], Mechanism of Nitrogen Excitation in the Night Sky, 442
Azarkh (R. M.), [Prof. A. E. Braunstein and], Transamination of *l*- and *d*-Amino Acids in Normal Muscle and in Malignant Tumours, 669

Babcock (E. B.), and G. L. Stebbins, jun., American Species of Crepis, 45
Bacharach (A. L.), Winton's The Structure and Composition of Foods. Vol. 4 (*Review*), 366; Ergebnisse der Vitamin- und Hormonforschung. Band 2 (*Review*), 1080
Baddeley (Dr. G.), Mesomerism and Orientation, 444
Bagot (J. H.), Juvenile Delinquency, 703
Bailar (J. C.), and J. P. McReynolds, Stereochemistry of Complex Inorganic Compounds, 1096
Bailey (Prof. E. B.), Dame Ogilvie Gordon, 142; Dr. W. B. Wright, 775
Bailey (M. A.), [death], 736; [obituary article], 890
Baker (Prof. R. H.), Astronomy: A Textbook for University and College Students. Second edition (*Review*), 899
Baker (William Morrant), centenary of the birth of; work of, 661
Baker (Wilson) and D. M. Bealy, Structure of the Dimeric Forms of *o*-*Iso*propenyl-phenols, 865
Baker (Z.), [H. E. Himwich, J. F. Fazekas and], Respiratory Metabolism of Infant Brain, 38
Bakker (G. J. T.), appointed acting chairman of the International Executive Council of the World Power Conference, 781
Balls (Prof. A. K.), and H. Lineweaver, Nature of a Group in Papain Essential to its Activity, 513
Banerjee (H. N.), [Dr. B. K. Kar and], Effect of Ethylene on *Mangifera indica*, 597
Banga (I.), S. Ochoa and Prof. R. A. Peters, Pyruvate Oxidation System in Brain, 74
Bannerman (Dr. D. A.), The Birds of Tropical West Africa, with Special Reference to those of the Gambia, Sierra Leone, the Gold Coast and Nigeria. Vol. 5 (*Review*), 364
Barbeau (M.), The Assomption Sash, 756
Barcroft (Sir Joseph), appointed a member of the advisory council to the Committee of the Privy Council for Scientific and Industrial Research, 665
Bardswell (N. D.), Tuberculosis in Cyprus, 362
Barnard (J. E.), Towards the Smallest Living Things, 80
Barnard (R. W.), General Analysis, 295
Barnard (W. G.), appointed professor of pathology at St. Thomas's Hospital Medical School, 219
Barnóthy (Dr. J.), and Dr. M. Forró, Directional Distribution of the Hard and Soft Component of Cosmic Radiation, 116
Barnum (Prof. H. H.), [death], 185
Barrett (Sir James), The Wyperfeld (Mallee) National Park, Victoria, 272
Barrois (Prof. C.), [death], 933
Barrow (Dr. F.), conferment upon, of the title of reader in chemistry by London University, 762
Barry (J. G.), [T. H. Johnson and], Cosmic Rays at High Altitude, 677
Bartels (Prof. J.), elected to the physical mathematical class of the Prussian Academy of Sciences, 70
Bartlett (Dr. M. S.), Statistics in Theory and in Practice (*Review*), 799
Bartlett (R. J.), Measurement in Psychology, 432; 498
Barton (R. F.), Philippine Pagans: the Autobiographies of Three Ifugaos (*Review*), 1077
Bartsch (P.), [W. H. Dall, H. A. Rehder and], Recent and Fossil Marine Pelecypod Mollusks of the Hawaiian Islands, 484
Basu (Minendra Nath), Bunas of Bengal, 789
Bate (Dr. A. E.), Formula for the Change of Velocity of Sound with Temperature, 479
Bate (Ruth C.), [B. P. Kaufmann and], Chromosome Rearrangements in *Drosophila melanogaster*, 121
Bates (Dr. G. H.), Polyploidy Induced by Colchicine and its Economic Possibilities, 315
Bates (Prof. L. F.), Modern Magnetism (*Review*), 399; Artificial Radioactivity (*Review*), 689
Baulig (Prof. H.), elected an honorary member of the American Geographical Society, 199
Bayon (Dr. H. P.), Ancient Tests for Pregnancy, 826
Bazalgette (H. L.), Victoria Falls Hydro-Electric Scheme, 1098
Beadle (D. G.), and H. S. Patterson, Effect of Tube-length on the Visibility of Dust Particles with an Oil-immersion Objective, 327
Beadle (Prof. G. W.), [Prof. A. H. Sturtevant and], An Introduction to Genetics (*Review*), 1067
Beaglehole (Ernest and Pearl), Tongan Colour-Vision, 983
Beakbane (A. B.), and E. C. Thompson, Anatomy of Apple Roots, 447
Beal (J. M.), Cytology and Taxonomy of Calochortus, 335
Beall (D.), Isolation of Œstrone from the Adrenal Gland, 76
Beard (H. H.), [C. J. Kelly and], Creatine as a Product of Methylation, 162
Beauchamp (J. W.), Function of the Electrical Supply Engineer in War-time, 914
Beck (Dr. W. A.), Determination of Growth-rates by the Optical Lever Method, 786
Beddard (Dr. A. P.), [death], 857
Beebe (Dr. W.), and Jocelyn Crane, Deep-Sea Fishes of Bermuda, 638
de Beer (Dr. G. R.), Experimental Embryology (*Review*), 493
Beeson (C. F. C.) and B. M. Bhatia, Biology of the Cerambycidæ, 120
Beghin (P.), Industry and Agriculture in Belgium, 188
Bell (O.), Sociological Aspects of the Cinema, 520
Benedict (C. B.), Ontogeny and Phylogeny of the Human Nose, 252
Benioff (Dr. H.), and Dr. B. Gutenberg, Observations with Electromagnetic Microbarographs, 478
Bennet-Clark (Prof. T. A.), and Miss Dorothy Bexon, Expression of Vacuolar Sap, 243
Bennett (A.), Vegetation of a South Westmorland Fell, 715
Bennett (E. G.), [R. L. Sanford and], Magnetic Testing, 838
Berenson (Mrs. Mary), A Vicarious Trip to the Barbary Coast (*Review*), 585
Berg (Dr. W. F.), Photography in Scientific Research, 356
Berkner (L. V.), Nature of Radio Fade-out, 947
Bernacchi (Comdr. L. C.), Saga of the *Discovery* (*Review*), 198
Bernal (Prof. J. D.), Science in a Changing World (*Review*), 3
Bernheim (Prof. F.), and J. E. Morgan, Photo-oxidation of Pyrrhole, 290
Berry (A. J.), Volumetric Analysis: including the Analysis of Gases; with a Chapter on Simple Gravimetric Determinations. Fifth edition (*Review*), 366
Bealy (D. M.), [Wilson Baker and], Structure of the Dimeric Forms of *o*-*Iso*propenyl-phenols, 865
Best (Prof. C. H.), awarded the Baly gold medal of the Royal College of Physicians, 242; and Prof. N. B. Taylor, A Text in Human Physiology (*Review*), 228; [Prof. D. Y. Solandt and], Role of Dietary Choline in Neurohumour Production, 376
Beust (Nora E.), Professional Library Education, 240
Bevan (E.), Symbolism and Belief (Gifford lectures), 196
Bexon (Miss Dorothy), [Prof. T. A. Bennet-Clark and], Expression of Vacuolar Sap, 243
Bessonoff (Dr. N.), and Mme. M. Woloszyn, Platinum Potential of Vitamin C Solutions in Contact with Molecular Oxygen, 289
Bhatia (B. M.), [C. F. C. Beeson and], Biology of the Cerambycidæ, 120
Bigger (Prof. J. W.), Man against Microbe (*Review*), 371
Bijl (Dr. A.), [Dr. A. Michels, Dr. J. de Boer and], Effect of an Excitation Energy on the Specific Heat of Liquid Helium II and its Relation to the Exchange Effect in a Non-Ideal Bose-Einstein Gas, 594
Bingham (E. C.), and S. D. Stookey, Fluidity and Temperature, 448

NAME INDEX

Binns (A. L.), Present Position of Technical Education in the West Riding, 84
Bish (P. E.), awarded the Earl of Durham prize of the Institution of Naval Architects, 546
Biswas (K.), and C. C. Calder, Hand-Book of the Common Water and Marsh Plants of India and Burma, 1936 (*Review*), 727
Bjerknes (Prof. J.), awarded the Symons gold medal of the Royal Meteorological Society, 1088
Blackett (Prof. P. M. S.), Instability of the Mesotron and the Gravitational Constant, 30
Blagoveschensky (V. A.), Weather Periodicities in Turkestan, 791
Blair (Dr. G. W. Scott), An Introduction to Industrial Rheology (*Review*), 197; and Miss F. M. V. Coppen, Differential Threshold for Compression Modulus, 286
Blake (M. A.), Fruit Breeding in the U.S.A., 209
Blakeslee (A. F.), Chemistry and Genetics, 120; [H. E. Warmke and], Sex Determination in Melandrium, 252; and A. G. Avery, Fifteen Years' Research on Datura, 253
Blanc (Dr. A. C.), Discovery of Neanderthal Man in Italy, 106
Bledisloe (Viscount), presidential address to the Museums Association, 124
Bloch (Dr. M.), [Dr. J. Dufay and], The Forbidden $^3P_2$–$^1D_2$ Line of O III in the Nebular Spectrum of Nova Herculis 1934, 593
Block (L. P.), [J. H. Simons and], Reaction of Fluorine with Carbon, 947
Bloomfield (L.), Linguistic Aspects of Science, 240
Blumenthal (E.), [J. B. M. Herbert and], Mechanism of Hydrolysis of Inorganic Esters, 248
Boas (Prof. F.), The Mind of Primitive Man. Revised edition (*Review*), 738
Boele (J.), awarded an R. L. Weighton memorial medal of the North-East Coast Institution of Engineers and Shipbuilders, 665
de Boer (Dr. J.). [Dr. A. Michels, Dr. A. Bijl and], Effect of an Excitation Energy on the Specific Heat of Liquid Helium II and its relation to the Exchange Effect in a Non-Ideal Bose-Einstein Gas, 594
Bogue (Prof. J. Yule), Sir Frederick Hobday, 184
Bohr (Prof. Niels), conferment upon, of an honorary doctorate by London University, 875; and Prof. R. Peierls and Dr. G. Placzek, Nuclear Reactions in the Continuous Energy Region, 200
Bolliger (A.), and A. Carrodus, Ambisexual Action of Progesterone as observed in the common Australian Opossum, 671; Effect of Œstrogens on the Pouch of the Marsupial *Trichosurus vulpecula*, 1049
Bolton (D. J.), Superimposed Control Applications with special references to Tariffs and Load Levelling, 126
Bomskov (Dr. C.), Methodik der Hormonforschung, Band 2 (*Review*), 192
Bond (C. J.), [death], 933; [obituary article], 1038
Bond (Dr. G.), Utilization of Carbohydrates in Leguminous Symbiosis, 906
Bond (G.), and J. Boyes, Nitrogenous Excretion from Root Nodules, 946
Bond (Dr. G.), [Dr. S. Williams and] Practical Botany: a First Year Course for University and Intermediate Science Students (*Review*), 739
Bonet-Maury (Dr. P.), and H. R. Olivier, Effect of Irradiating the Tubercle Bacillus with Radon, 833
Bonner (J.), [J. English, A. J. Haagen-Smit and], Wound Hormones in Plants, 984
Bonner [Kirby Smith and], Raman Spectrum of Gaseous Methylamine, 1018
Booth (H. S.), S. G. Frary and F. B. Dutton, Fluorination of Phosphorus Halides, 1017
Bor (N. L.), Vegetation of the Aka Hills, Assam, 39
Borghs (J.), [Prof. A. van Itterbeek, W. van Dingenen and], Adsorption of Helium Gas on Active Charcoal between 4·2° and 1·78° K., 249
Borgström (G.), Formation of Cleistogamic and Chasmogamic Flowers in Wild Violets as a Photoperiodic Response, 514
Boring (E. G.), H. S. Langfeld, H. P. Weld and others, Introduction to Psychology (*Review*), 744
von Borries and E. Ruska, The Electron Microscope and the Investigation of Viruses, 40
Bosazza (V. L.), Occurrence of Wax-like Substances in Peaty Fireclay, 835
Bose (S. R.), Vacuolar Stain in Fungal Hyphæ, 80
Bostrøm (Dr. K. J.), Dr. J. Koch and Dr. T. Lauritsen, Delayed Neutron Emission accompanying Uranium Fission, 830
Boswell (Prof. P. G. H.), The Earth's Crust: its Fabric and Foundations (*Review*), 403
Bourne (M. C.), and H. Grüneberg, Inheritance of Cataract, 38
Bovey (Dr. W.), presented with the Lorne Pierce medal of the Royal Society of Canada, 255
Bowen (Marjorie), Ethics in Modern Art (Conway Memorial Lecture) (*Review*), 1082
Bower (Prof. F. O.), Botany of the Living Plant. Third edition. With the assistance of Prof. J. M. F. Drummond and Dr. G. Bond (*Review*), 400
Bowman (Dr. I.), Science and Social Pioneering, 565
Boyd (Dr. W. C.), Blood Group Tables, 321
Boyer (C. B.), The Concepts of the Calculus: a Critical and Historical Discussion of the Derivative and the Integral (*Review*), 802
Boyes (J.), [G. Bond and], Nitrogenous Excretion from Root Nodules, 946
Boyland (Dr. E.), [Prof. A. C. Chibnall, M. W. Rees. G. R. Tristram, E. F. Williams and], The Glutamic Acid of Tumour Proteins, 71
Boyle (P. J.), [Prof. E. J. Conway and], A Mechanism for the Concentrating of Potassium by Cells, with Experimental Verification for Muscle, 709; [Prof. E. J. Conway, Dr. F. Kane, H. O'Reilly and], Localization of Electrolytes in Muscle, 752
Braak (Dr. C.), Fog in the Netherlands, 947
Braddick (Dr. H. J. J.) and G. S. Hensby, Evidence for the Occurrence of Meson Pairs, 1012
Bradfield (Major-Gen.), An Indian Medical Review, 1087
Bragg (Sir William), History in the Archives of the Royal Society (Pilgrim Trust Lecture), 21; X-Ray Analysis and the Structure of Matter, 961; re-elected president of the Royal Society, 976
Bragg (Prof. W. L.), elected a *correspondant* of the Paris Academy of Sciences, 150
Brandenberger (Dr. E.), Angewandte Kristallstrukturlehre: Ein Hilfsbuch zur Bestimmung von Kristallstrukturen (*Review*), 587
Brandon (Dorothy), Rose Propagation, 1096
Brandstatter (Dr. V.), [death], 236
Braun (Dr. W.), An Experimental Attack on some Problems of Physiological Genetics, 114
Braunholtz (H. J.), Archæology in Peru: Recent Progress, 841
Braun-Menéndez (E.), [J. M. Muñoz, J. C. Fasciolo, L. F. Leloir and], Hypertensin: the Substance causing Renal Hypertension, 980
Braunstein (Prof. A. E.), and R. M. Azarkh, Transamination of *l*- and *d*-Amino Acids in Normal Muscle and in Malignant Tumours, 669; and S. M. Bychkov, A Cell-free Enzymatic Model of *l*-Amino-acid Dehydrogenase ('*l*-Deaminase'), 751
Breder (C. M.), and E. B. Gresser, The four-eyed Blenny, 675
Bredereck (Dr. H.), und Dr. R. Mittag, Vitamine und Hormone: und ihre technische Darstellung. Teil 1. Zweite Auflage (*Review*), 739
Breit (G.), H. M. Thaxton and L. Eisenbud, Scattering of Protons by Protons, 254
Brezina (E.), W. Hellpach, R. Hesse, E. Martini, B. de Rudder, A. Schittenhelm, A. Seybold and Prof. L. Weickmann, Herausgegeben von H. Woltereck. Klima, Wetter, Mensch (*Review*), 1066
Brierley (Prof. W. B.), The Royal Agricultural Show, 61
Brierly (J. L.), Encirclement (*Review*), 1031
Briggs (Dr. L. H.), Constitution of Solasonine (Solanine-*s*), 247

Briggs (Dr. L. J.), Standards of Physical Measurement (*Review*), 458
Brightman (R.), Youth and National Service (*Review*), 723
Brigl, Gronemeier and Schultz, The Ethyl-Thioglucosides and a New Monoacetoneglucose, 680
Brimble (L. J. F.), Intermediate Botany. Second edition (*Review*), 739
Brindley (Dr. G. W.), and Dr. G. H. Atkinson, Effect of Temperature on the Intensity of X-Ray Reflections from Copper, 477
Bristow (Col. W. A.), Fuel Industry in Great Britain, 825
Bristowe (Dr. W. S.), The Comity of Spiders. Vol. 1 (*Review*), 895
Britton (K.), Pragmatical Logic (*Review*), 880
Broda (Dr. E. E.), Dr. C. F. Goodeve, Dr. R. J. Lythgoe and E. Victor, Cataphoretic Measurements on Solutions of Visual Purple and Indicator Yellow, 709
de Broglie (Prof. L.), Le Principe de Correspondance et les Interactions entre la Matière et le Rayonnement, 544
de Broglie (Maurice), Atomes, radioactivité, transmutations (*Review*), 689
Brohult (S.), and S. Claesson, Dissociation of the Hæmocyanin Molecule, 111
Brooks (Dr. C. E. P.), Climate and Man (*Review*), 1066
Brooks (Prof. F. T.), conferment upon, of an honorary doctorate by St. Andrews University, 605
Brose (D. T.), and A. Caliver, Negro Education in the United States, 293
Brough (J.), appointed lecturer in the zoology of vertebrates in Edinburgh University, 47; The Triassic Fishes of Besano, Lombardy (*Review*), 615
Brough (Dr. P.), Avoidance of Crystal Formation during embedding of Plant Material in Paraffin Wax, 250
Brown (Sir Edward), [death], 318
Brown (E.), Students and Military Training, 17
Brown (Leslie), Outlaw of the Air (*Review*), 1079
Brown (O. F.), and E. L. Gardiner, The Elements of Radio-Communication. Second edition (*Review*), 1068
Brown (Dr. T. W. F.), awarded an engineering gold medal of the North-East Coast Institution of Engineers and Shipbuilders, 665
Brown (Dr. William), War and Peace: Essays in Psychological Analysis (*Review*), 845
Brown (Dr. W. H.), [death], 970
Browne (F. L.), [E. Sutermeister and], Casein and its Industrial Applications. Second edition (*Review*), 584
Brownlee (A.), [R. G. Linton and], Vitamin A content of the Livers of a Hundred Healthy Dogs, 978
Bruce (Brig.-Genl. the Hon. C. G.), [death], 143; [obituary article], 407
Bruce (Miss Maye), Modification of the Steiner Composting Process, 280
Brunt (Prof. D.), Atmospheric Turbulence (*Review*), 651
Buchsbaum (Dr. R.), Animals without Backbones: an Introduction to the Invertebrates (*Review*), 847
Buddin (W.), Hot Water Treatment of Iris Bulbs, 716
Buller (Prof. A. H. R.), Symbiosis between Fungi and Scale Insects (*Review*), 531
Bullough (W. S.), and Dr. R. Carrick, Spring Development of the Gonads of the Starling (*Sturnus v. vulgaris* L.), 33
Burbank (Luther), An Architect of Nature: being the Autobiography of, with Biographical Sketch by W. Hall (*Review*), 896
Burk (Dr. D.), appointed senior chemist in the National Cancer Institute, U.S. Public Health Service, and associate professor of biochemistry at Cornell University, 282
Burkill (I. H.), [Sir David Prain and], An account of the genus Dioscorea in the East. Part 2: The Species which twine to the Right; with Addenda to Part 1, and a Summary (*Review*), 895
Burns (Prof. D.), Assessment of Physical Fitness, 431; 466
Burr (Dr. M.), The Insect Legion (*Review*), 739
Burt (Prof. C. L.), conferment upon, of an honorary doctorate by Aberdeen University, 127; Prof. S. Freud, 735
Burt (Dr. J. Barnes), elected interim chairman of the International Society of Medical Hydrology, 1087
Buss (Prof. A.), [death], 812
Butenandt (Prof. A.), elected to the Physical Mathematical Class of the Prussian Academy of Sciences, 70; awarded the Nobel prize for chemistry for 1939; work of, 858
Butler (C. G.), Choice of Water by the Honey Bee, 984
Butler (H. B.), conferment upon, of an honorary doctorate by Edinburgh University, 87
Butler (Dr. J. A. V.), The Fundamentals of Chemical Thermodynamics. Part 1: Elementary Theory and Electrochemistry. Third edition (*Review*), 584
Buxton (Prof. J. B.), and R. E. Glover, Tuberculin Tests in Cattle, 108

TITLE INDEX

Aberdeen University, conferment of honorary doctorates on Prof. C. L. Burt and Prof. A. Law, 127
Abortion, Report on, 19
Academy of Natural Sciences, Philadelphia, award of the Hayden Memorial Geological medal of the, to Sir Arthur Smith Woodward, 1010
Accidents, Toll of, 504
Acclimatisation, Reactions of, and of Non-Adaptation, Prof. M. Piery and Prof. J. Enselme, 731
Acetate Oxidation, Vitamin B_1 and, by Bacteria, Dr. J. H. Quastel and D. M. Webley, 633
Acetone, Thermal Decomposition of, J. G. Davoud and Prof. C. N. Hinshelwood, 909
Acetylphosphate and Pyruvate Oxidation, Dr. S. Ochoa, Prof. R. A. Peters and Dr. L. A. Stocken, 750
Acoustics of Buildings, [1839], 526
Actinium K, β Spectrum of, Mlle. M. Perey and M. Lecoin, 326
Activation, Co-operative, Prof. W. E. Garner, 287
Adelaide: Institute of Medical and Veterinary Science, opening of new laboratories, Sir Charles Martin, 392
Adenosinetriphosphatase, Myosine and, Prof. W. A. Engelhardt and M. N. Ljubimowa, 668
Adsorption, Very Slow, A Possible Explanation of, K. S. Gururaja Doss, 448
Adventure, The Spirit of, 580
Aequanimitas, with other Addresses to Medical Students, Nurses and Practitioners of Medicine, late Sir William Osler. Reprinted from the third edition. Biographical note by Sir Walter Langdon-Brown (*Review*), 899
Aeronautical: Research: Wind Tunnels, Old and New, Dr. G. W. Lewis (Wilbur Wright memorial lecture), 229; Computation, Use of Matrices in (*Review*), 650
Africa: Tropical West, The Birds of, with special reference to those of the Gambia, Sierra Leone, the Gold Coast and Nigeria, Dr. D. A. Bannerman. Vol. 5 (*Review*), 364; Central and Southern, Physiographical Development of, F. Dixey, 676; Capital Investment in, its Course and Effects, Prof. S. H. Frankel (*Review*), 686; Commercial Development of (*Review*), 686
African: Linguistics, 437*; Women: a Study of the Ibo of Nigeria, Mrs. Sylvia Leith-Ross (*Review*), 737; Studies, Research on, 779; Genesis, Dr. L. Frobenius and D. C. Fox (*Review*), 894
Ageing: Problems of, Biological and Medical Aspects, Edited by E. V. Cowdry (*Review*), 995
Agricultural Economics, International Bibliography of, No. 1, 68
Agricultural: Research Institutes, Reports on work of, 241; Education Association: Annual Conference at Belfast, 257; Libraries, International Directory of, 546
Agriculture: Modern, Science in, 49; and Fisheries, Minister of, W. Gavin appointed agricultural adviser designate to the, 410; Scientific Research and, Sir Thomas Middleton, 616
Airplane Structures, Prof. A. S. Niles and Prof. J. S. Newell. 2 Vols. Second edition (*Review*), 898
Air: Raid Defence League, Second Bulletin of the, 66; Liner, New Long-Distance, 105; *Raid Defence*, June, 145; Sterilisation, Evaporation of Mist Particles and its bearing on, S. R. Finn and E. O. Powell, 864
Aka Hills, Assam, Vegetation of the, N. L. Bor, 39
Akwarium, The Warsaw, 591
β-Alanine, Activity of, in Stimulating Growth of Young Rats in a Diet Deficient in 'Filtrate Factor', M. Hoffer and Prof. T. Reichstein, 72
Alcohol and Crime, Dr. W. N. East, 703
Alcoholism and Mental Disease, Dr. A. Le Gall, 543; and Suicide, Dr. M. Moore, 1040
Alga, Triploid Red, Kathleen M. Drew, 209
Alkali and Alkaline Earth Metals, Chemistry of the (*Review*), 1064
Alkyl: Halides, Hydrolysis of, R. A. Ogg, jun., 519; Chain Length, Dipole Moment and, Dr. H. O. Jenkins, 667
Alsea Ethnography, P. Drucker, 714
Alternating Currents: Essentials of, Prof. W. H. Timbie and Prof. H. H. Higbie. Second edition (*Review*), 585; for Long-Distance Transmission, Possibilities of, H. Rissik, 988
Aluminium Alloys, Selective Oxidation of, Prof. S. Dobiński and M. Niesluchowski, 510
Amarah West, Sudan, Excavations at, 1938–39, 43
America: The Royal Visit to, 15; Central, Early Cultural Relations in, 505
American: Museum Methods, Miss Ruth Weston, 19; Geographical Society: awards made to Prof. E. de Martonne, Prof. H. J. Fleure, J. R. Rymill, Sir Wilfred Grenfell, Prof. H. Baulig, and Prof. G. Dainelli, 199; E. Antévs, Prof. L. L. Mecking, W. E. Rudolph, P. G. Schott, and Dr. L. Dudley Stamp elected corresponding members of the, 199; award of the David Livingstone centenary gold medal to, J. Rymill, 546; Genetic Association, award of the Meyer medal of the, to Dr. D. Fairchild, 236; *Journal of Anatomy*, Prof. G. W. Corner appointed editor of the, 508; Association, Dr. A. B. Sabin presented with the Theobald Smith award of the, 546; Society of Plant Physiology, award of the Charles R. Barnes honorary life membership of the, to Prof. L. Jost, 282; Mineral Deficiencies, Sir Thomas Holland (*Review*), 921; Congress of Physical Therapy, award of a gold key of the, to Dr. J. B. Mennell, 976; Public Health Association, presentation of the Sedgwick medal of the, to Dr. T. Parran, 1010; Women's Chemical Honor Society, Iota Sigma Pi, Dr. Mary Evelyn Laing McBain elected national president of the, 1044; Scientific Congress, Eighth, preparations for the, 1056
α-Amino Acid Esters, Poly-condensation of, Dr. M. Frankel and E. Katchalski, 330
α-Amino-Acid Esters, Carbamates of, and their Polycondensation, Dr. M. Frankel, O. Neufeld, and E. Katchalski, 832
α-Amino-Acid Oxidase Content of Rat Tissues in Riboflavin Deficiency, Reduction of the, A. E. Axelrod, H. A. Sober and Prof. C. A. Elvehjem, 670
l-Amino-Acid Dehydrogenase ('*l*-Deaminase'), A Cell-free Enzymatic Model of, Prof. A. E. Braunstein and S. M. Bychkov, 751.
l- and *d*-Amino Acids, Trans-amination of, in Normal Muscle and in Malignant Tumours, Prof. A. E. Braunstein and R. M. Azarkh, 669
Amino: -Acids and Rooting of Cuttings, B. W. Doak, 379; and Bisamino-Methylenecamphors, Difference in Odour of *d*-, *l*- and *dl*-derivatives of, Dr. Bawa Kartar Singh and Awadh Behari Lal, 910; Acids and Proteins, The Chemistry of the, edited by Prof. C. L. A. Schmidt (*Review*), 923
Ampere, The Absolute, H. L. and R. W. Curtis and C. L. Critchfield, 294
Amphioxus, Amylase in, Prof. W. L. Doyle, 867
Anæsthetic Practice, Modern, edited by Sir Humphry Rolleston and Dr. A. A. Moncrieff (*Review*), 370

Analyse mathématique, P. Appell. Cinq. édition. Tome 2 (*Review*), 369
Analysis: Theoretical Qualitative, Prof. J. H. Reedy (*Review*), 365; Organic, Systematic Qualitative, H. Middleton (*Review*), 366; Volumetric, including the analysis of Gases, with a chapter on Simple Gravimetric Determinations, A. J. Berry. Fifth edition (*Review*), 366; Qualitative, Introductory, Prof. W. C. Vosburgh. Revised edition (*Review*), 367
Anatomy: Practical, A Manual of, a Guide to the Dissection of the Human Body, Prof. T. Walmsley. Second edition. In 3 Parts. Part 2 (*Review*), 896; Inspector of, in England, Scotland and Wales, Dr. E. Ellice Henderson appointed, 1088
Anavysos Kouros, The, Dr. A. Philadelphus, 278
Ancient House Types in Arizona, Dr. F. H. H. Roberts, jun., 556
'Anderson' Shelters, Official Tests of, 238
Andesite, Melting of Granodiorite by, E. S. Larsen and G. Switzer, 676
Anglo-Saxon Burials in Rutland, 146; Ship Burial, 239; Tradition, The, Prof. G. Catlin (*Review*), 398; –Egyptian Sudan, appointment of G. Andrew as Government geologist in the, 1010
Animal: Behaviour, D. Seth-Smith, 85; Tissue Cells, Nature of the Growth-accelerating Substance of, Dr. A. Fischer, 113; and Bird Painting: the Outlook and Technique of the Artist, C. Simpson (*Review*), 373; Ecology and Taxonomy, A Laboratory Introduction to, Prof. O. Park, Prof. W. C. Allee and Prof. V. E. Shelford (*Review*), 583; Physiology, An Introduction to, W. B. Yapp (*Review*), 766; Breeding in the light of Genetics, Dr. J. E. Nichols, 818; Welfare, Science and, 827; Families and where they live, Arnrid Johnston (*Review*), 1078
Animalium Cavernarum Catalogue, pars 14, 974
Animals: The Social Life of, Prof. W. C. Allee (*Review*), 5; and Air Raids, 503; during War-time, 661; without Backbones: an Introduction to the Invertebrates, Dr. R. Buchsbaum (*Review*), 847
Anopheles Mosquito, Female, Mouth-parts of the, G. G. Robinson, 870
Anserine in Muscle: Possibility of Determination by Titration, Dr. E. C. Bate Smith, 1015
Antarctic: Expedition, Projected, 825; History, On some Misrepresentations of, A. R. Hinks, 901
Ant-hill, Temperature Rhythm in an, M. Katô, 385
Anthologia Anthropologica (*Review*), 698
Anthropoid Apes, Taste-testing the, Prof. R. A. Fisher, Dr. E. B. Ford and Dr. J. S. Huxley, 750
Anthropological: Studies, Cultural Significance of, Prof. H. J. Fleure, 697; Studies in India, 721; Periodical in India, New, 745
Anthropology: Physical, Scope and Limitations of, Prof. W. E. Le Gros Clark, 430; 804; Physical, and Problems of Modern Society, 797
Anthropometry and the War, Capt. A. G. Pape, 933
Antiquities in British Dependencies, Conservation of, 261
Antiquity, Dec., 1040
Antirrhinum Rust, Dr. A. Fikry, 913
Aphidophagous Syrphidæ, Hymenopterous Parasites of, M. Kamal, 639
Apia Observatory, Report for 1935, 828
Appendicitis: a Statistical Study, Dr. M. Young and W. T. Russell, 452; Causation of, 452
Apple: Market Economics of the, J. R. Raeburn, 385; Roots, Anatomy of, A. B. Beakbane and E. C. Thompson, 447; Canker, R. W. Marsh, 913; Vascular Anatomy of the, Mary MacArthur and R. H. Wetmore, 1053
Aquatic Plants of India and Burma, C. E. C. Fischer (*Review*), 727
Aqueous Solutions, The Oxidation States of the Elements and their Potentials in, Prof. W. M. Latimer (*Review*), 367
Arabian Sea, Marine Deposits of the, Dr. H. G. Stubbings, 841
Archæological: Survey of India, A Report on the Work of the, Sir Leonard Woolley, 758; finds in Staffordshire, Recent, 936
Archæology in Peru: Recent Progress, H. J. Braunholtz, 841; and Society, Dr. Grahame Clark (*Review*), 1077
Arctic: Ice and Snow, Life in, E. Kol, 39; Plants in the British Isles, Dr. N. Polunin, 352
Argentine National Department of Health, Dr. J. J. Spangenberg nominated president of the, 938
Armadillidium vulgare Latr., Monogenic broods in, H. W. Howard, 979
Armaments Race, Mathematics of the, Prof. H. T. H. Piaggio (*Review*), 692
Aromatic Polynitro Compound–Hydrocarbon Complexes, Structure of, H. M. Powell and G. Huse, 77
Artesian Well in Paris, [1839], 720
Arthritis in Wild Mammals, H. Fox, 638
Artists' and Decorators' Materials, The Scientific Aspects of, Dr. R. S. Morrell (*Review*), 175
Ascorbic Acid, Role of Manganese in the Biological Synthesis of, M. N. Rudra, 868
Asia and Europe: The Native Races of, A Copious Selection of Passages for the Study of Social Anthropology from the Manuscript Notebooks of Sir James George Frazer. Arranged and edited from the MSS, by R. A. Downie (*Review*), 688
Assam, Flora of. Vol. 3, U. N. Kanjilal, A. Das, P. C. Kanjilal and R. N. De (*Review*), 894
Assomption Sash, The, M. Barbeau, 756
Astrolabe, Dumont d'Urville's Voyage in the, [1839], 219
Astronomical Navigation, An Introduction to, P. H. Legg (*Review*), 586
Astronomy: a Textbook for University and College Students, Prof. R. H. Baker. Second edition (*Review*), 899; Old and New, Sir Richard Gregory, Bt. (*Review*), 1028; in Ancient Egypt, 1041
Astrophysics, Analytical, Prof. W. H. McCrea (*Review*), 130
Athens, Medical School at, [1839], 644
Atlantic Submarine Valleys, R. A. Smith, 1042
Atmosphärische Turbulenz, Dr. H. Lettau (*Review*), 651
Atmospheric: Pollution, Twenty-fourth Report on, 167; Turbulence, Prof. D. Brunt (*Review*), 651
Atomes, radioactivité, transmutations, M. de Broglie (*Review*), 689
Aurora Islands, Re-discovery of the, [1839], 127
Australia: Wild Flowers of, Thistle Y. Harris (*Review*), 7; Fisheries Research in, Sir David Rivett, 312; Arnhem Land, Totemic Ceremonial in, Dr. D. F. Thomson, 319; Central, The Native Tribes of, late Sir Baldwin Spencer and late F. J. Gillen. New edition (*Review*), 363
Australian Wild Flowers, Some Eastern, Prof. T. G. B. Osborn (*Review*), 7
Australasia; including Australia, New Zealand, Oceania, New Guinea and Indonesia: The Native Races of, A Copious Selection of Passages for the Study of Social Anthropology from the Manuscript Notebooks of Sir James George Frazer. Arranged and edited from the MSS. by R. A. Downie (*Review*), 688
Australasian Antarctic Expedition, Reports of the, 589
Australopithecus (Plesianthropus), Dentition of, Dr. W. K. Gregory and M. Hellman, 451
Autocatalysis and Blood Coagulation, Dr. T. Astrup, 76
'Auto-parasitism' by *Nemeritis canescens* (Grav.) (Ichneumonidæ), E. S. Narayanan, 207
Auxiliary Territorial Service, Army Branch, Dame Helen Gwynne-Vaughan appointed director of the, 70
Avian Sternum, The, Honor B. Fell, 557

Baade and Zwicky's theory of Cosmic Rays, and the Helium content of Beryls, Dr. J. Read, 1046
Bacteria of the Throat and Nose, Drs. Edith Straker, B. Hill and R. Lovell, 1017
Bagh Caves in Gwalior State, Technique of the Painting Process in the, S. Paramasivan, 554
Balloon Experiments in High Latitudes, H. Carmichael and E. G. Dymond, 294

Bananas, Cercospora Leaf Spot Disease of, Dr. C. W. Wardlaw, 11
Bantu, Southern, Cattle and Marriage among, J. D. Krige, 912
Barbary Coast, A Vicarious Trip to the, Mrs. Mary Berenson (*Review*), 585
Barnacle Communities, F. Hiro, 1017
Basque Origins, R. Gallop, 946
Bedford College for Women, A History of, 1849–1937, Dr. Margaret J. Tuke (*Review*), 132
Bees, North American, of the Genus Osmia, Grace A. Sandhouse, 870
Beit Memorial Fellowships for Medical Research, 215
Belfast, Queen's University, Dr. R. H. Sloane appointed lecturer in Experimental Physics and G. Williams lecturer in zoology, 47
Belgium, Industry and Agriculture in, P. Beghin, 188
Benares Hindu University, Pharmaceutical Association of, Dr. G. Domagk elected an honorary member of the, 938
Benzedrine and Brain Metabolism, P. J. G. Mann and Dr. J. H. Quastel, 943
Benzpyrene Tumour Strain, a, in Hamsters with Tendency to Metastasis Formation, L. Halberstaedter, 377
Bern University, award of the international prize for researches on encephalitis to Dr. B. Disertori, 1044
Beryls, Helium content of, Baade and Zwicky's theory of Cosmic Rays, and the, Dr. J. Read, 1046
Beta Upper Energy Limits, Evaluation of the, with simple absorption data, J. B. R. Rajam, P. C. Capron and Prof. M. de Hemptinne, 202
Betsileo (Madagascar), Monographie des, H.-M. Dubois (*Review*), 894
Bibliographies, World Bibliography of, forthcoming, 69
Bile Production in Tumour-bearing Mice and the use of Bile in Filtration, Dr. L. Dorothy Parsons, 75
Binocular Stereoscopic Vision, Sir Richard Paget, Bt., 153; Rev. W. McEntegart, 154
Biochemistry: for Medical Students, Dr. W. V. Thorpe (*Review*), 268; Outlines of, the Organic Chemistry and the Physicochemical Reactions of Biologically Important Compounds and Systems, Prof. R. A. Gortner. Second edition (*Review*), 268; The Realm of (*Review*), 268
Biological Principles, Introducing, T. H. Hawkins (*Review*), 847
Biologists, Applied, Society of, 240
Biology: Supply and Training of Teachers in, Prof. J. Ritchie, 129; 140; School, and Citizenship, 129; The School and Society, T. H. Hawkins, 140; Everyday, An Introduction to the Study of Life, Dr. G. Pugh Smith (*Review*), 191; Rhythmic Processes in, Dr. K. Mellanby, 560; General Science, A. Spencer White (*Review*), 896; Philosophical, Essays in, late Prof. W. M. Wheeler, selected by Prof. G. H. Parker (*Review*), 1078
Biotin, Thiamin and, Excretion of, by the Roots of Higher Plants, P. M. West, 1050
Birds: Wild, Protection of, 590; British, The Handbook of, Vol. 3 (Hawks to Ducks). H. F. Witherby (Editor), Rev. F. C. R. Jourdain, N. F. Ticehurst and B. W. Tucker (*Review*), 691; of Britain: (*Review*), 691; Rev. F. C. R. Jourdain; S. G., 942
Birmingham: University, Prof. B. L. Goodlet appointed professor of Electrical Engineering; Gifts from Rubery Owen, Ltd., J. R. H. Sumner and the Birmingham Small Arms Co., Ltd., 87; Mechanics' Institution [1839], 1024
Birth Customs in East Anglia, Miss Barbara Newman and L. Newman, 412
Births, Deaths and Marriages, Statistics of, [1839], 87
Black-out, Factories and the, H. W. Cremer and others, 1023
Blenny, The Four-eyed, C. M. Breder and E. B. Gresser, 675
Blood: Coagulation, Autocatalysis and, Dr. T. Astrup, 76; Group Tables, Dr. W. C. Boyd, 321; -group Tests of Paternity, Report of House of Lords Select Committee on; Dr. V. Friedenreich and others, 542; Groups: among Primitive Peoples, 714; in Africa, Dr. R. Elsden-Drew, 789; Groups, Surnames and, Prof. R. A. Fisher and Miss Janet Vaughan, 1047
Borden Company, Dr. Icie Nacy-Hoobler awarded the gold medal and prize of the, 781
Borneo Jungle: An Account of the Oxford Expedition to Sarawak, J. Ford, C. M. Hartley, T. Harrisson, P. M. Synge and E. Shackleton. Edited by T. Harrisson (*Review*), 742
Bose-Einstein Gas, Non-Ideal, Effect of an Excitation Energy on the Specific Heat of Liquid Helium II and its relation to the Exchange Effect in a, Dr. A. Michels, Dr. A. Bijl and Dr. J. de Boer, 594
Botany: An Introduction to: Prof. A. W. Haupt (*Review*), 492; with special reference to the structure of the Flowering Plant, Prof. J. H. Priestley and Lorna I. Scott (*Review*), 492; University, First Year (*Review*), 492; Economic, Application of, in the Tropics, Sir Frank Stockdale, 563; Intermediate, L. J. F. Brimble. Second edition (*Review*), 739; Practical, A First Year Course for University and Intermediate Science Students, Dr. S. Williams and Dr. G. Bond (*Review*), 739
Brain: Pyruvate Oxidation System of, Necessity of Magnesium in the, Dr. S. Ochoa, 834; Metabolism, Benzedrine and, P. I. G. Mann and Dr. J. H. Quastel, 943
Brass, Impurities in, H. B. Gardner and C. M. Saeger, 386
Brazil, Anthropological Expedition to, Preliminary Report of an, 626
Britain, A National Atlas of, Prof. E. G. R. Taylor, 929
British: Museum (Natural History), Acquisitions, 18; Philosophy: A Century of, Dr. T. Greenwood (*Review*), 51; A Hundred Years of, Dr. R. Metz. Translated by Prof. J. W. Harvey, Prof. T. E. Jessop, H. Sturt. Edited by Dr. J. H. Muirhead (*Review*), 51; Non-Ferrous Metals Research Association, Dr. H. Moore, 83; Museum (Bloomsbury), Recent additions to the, 106; Empire Cancer Campaign, Grants from the, 109; Standards for A.R.P. Requirements, 109; Empire Naturalists' Association, H. Main elected national president of the, 185; Museum (Natural History), recent acquisitions, 188; School of Archæology at Athens, 1935–36, 278; Islands, The, and their Vegetation, Prof. A. G. Tansley (*Review*), 305; Speleological Association, Annual Conference of the, presidential address of Dr. R. R. Marett, 319; Association: at Birmingham [1839], 342; The Dundee meeting of the, General Arrangements and Sectional Programmes, 387; Democracy, Traditions and Future of, Harold Macmillan (*Review*), 398; Association: 1839, 453; election of Sir Richard Gregory, Bt., as president for 1940, 472; in War-Time, 579; Museum (Natural History), Recent acquisitions, 779; 937; Empire, The, H. V. Hodson (*Review*), 1031; University Thesis Literature, Accessibility of, Col. L. Newcombe, 1041; Plant Diseases, List of Common Names of, 1043; Social Hygiene Council. 1086; Sir Walter Langdon-Brown appointed president of the, 1088
Broad Bean Roots, Growing Tips of, Comparison of the Lethal Effect of Fast Neutrons and Gamma-Rays on the, Dr. L. H. Gray, Dr. J. Read and Dr. J. C. Mottram, 478
Broadcasting: and Television, Progress made in, Sir Noel Ashbridge, 322; over the Power Mains, 361
Broccoli, Food Value of, E. Vanstone and C. E. H. Knapman, 335
Brompton Hospital Reports. Vol. 7, 1938 (*Review*), 371
Bronze Age Cairns in Wales, Two, Sir Cyril Fox, 518
Buddha, Reincarnated, at Lhasa, Arrival of the, 826
Budgerigar, 'Dominant Grey', The Colour-producing Structure in the, Dr. L. Auber, 157
Building: Research, Progress in, 339; Modern, Principles of, Vol. 1: Walls, Partitions and Chimneys, R. Fitzmaurice (*Review*), 459; Recommendations (*Review*), 459
Bulbs, Diseases of, W. C. Moore (*Review*), 1075
Bunas of Bengal, Minendra Nath Basu, 789
Bush Fires in Victoria, 97
Business Management Books, Guide to, G. E. Milward. Seventh edition (*Review*), 372

Caddis Flies, The (Trichoptera): A Collector's Handbook, M. E. Mosely (*Review*), 364

Caerleon, Excavations at, 473

Calcium: Superphosphate, Manufacture of (*Review*), 848; Superphosphate and Compound Fertilisers: their Chemistry and Manufacture, P. Parrish and A. Ogilvie (*Review*), 848; in Ciliary and Muscular Movement, Dr. G. S. Carter, O. Gatty, Dr. J. H. Schulman and Dr. H. Walston, 980

Calculus: Prof. F. H. Miller (*Review*), 585; A Critical and Historical Survey of the (*Review*), 802; The Concepts of the, a Critical and Historical Discussion of the Derivative and the Integral, C. B. Boyer (*Review*), 802

Calf Thymus Nucleohistone, Physical Characterization of, Dr. R. Owen Carter and Dr. J. L. Hall, 329

California: Crustal Structure of, P. Byerly, 639; Stratigraphical Studies of (*Review*), 1030

Californian Deserts: The, A Visitor's Handbook, E. C. Jaeger; with chapters by S. S. Berry and M. J. Rogers. Revised edition; Prof. J. S. Gardiner (*Review*), 460

Callendar Steam Tables, Abridged, late Prof. H. L. Callendar, revised by G. S. Callendar. Fourth edition (*Review*), 1069

Calochortus, Cytology and Taxonomy of, J. M. Beal, 335

Cambridge: Observatory, Report for 1938-39, 747; University: Prof. D. M. S. Watson appointed Herbert Spencer lecturer for 1940, 47; R. H. Whitby awarded the Busk studentship in aeronautics, 199; P. Vellacott elected Master of Peterhouse, 242; J. C. Colbeck elected John Lucas Walker student and A. F. Huxley Michael Foster student; Dr. K. C. Dixon awarded the E. O. Fearnsides scholarship, 301; E. S. Shire appointed lecturer in physics and B. G. Wilkinson Frank Smart student of botany, 762; Expedition to Jamaica, Dr. V. J. Chapman, 964; Dr. H. McCombie appointed temporary director of the laboratory of General and Organic Chemistry, 990

Camouflage (Advisory Committee), 745

Canada: Royal Society of, Annual Meeting, award of the Flavelle medal to the late Prof. J. P. McMurrich; presentation of the Lorne Pierce medal to Dr. W. Bovey and of the Tyrrell medal to Dr. E. Z. Massicotte, 255; House-Sparrow in, R. L. Weaver, 983; Scientific and Industrial Research in, 1020

Cancer: Research Fund: Imperial, New Laboratories, 16; 41; Congress, Third International, Prof. F. C. Wood, 839

Carbohydrate and Potassium Metabolism in Normal and Adrenalectomized Animals, Connexion between, Prof. F. Verzár and J. C. Somogyi, 1014

Carbon: Disulphide, Anomalous Thermal Expansion of, at Low Temperatures, Dr. J. Mazur, 328; Compounds Chemistry of the, V. von Richter. Edited by the late Prof. R. Anschutz. Vol. 2 translated by Prof. A. Butenandt and others. Revised by T. W. J. Taylor and Dr. A. F. Millidge. Third edition (*Review*), 349; Disulphide Vapour, Detection of, 386; Reaction of Fluorine with, J. H. Simons and L. P. Block, 947

Carbonic Anhydrase, Prof. D. Keilin and Dr. T. Mann, 442

Cardigan Bay, Sand and Shingle formation in, J. A. Steers, 946

Caridea of the John Murray Expedition, Dr. W. T. Calman, 715

Carnegie: United Kingdom Trust, Report for 1938, 187; Institution, Washington, Prof. G. W. Corner appointed director of the Department of Embryology of the, 1088

Carrier Telephone Systems, Extensions of, N. Shinohara, Y. Hirano and M. Yoshioka, 545

Casein and its Industrial Applications, E. Sutermeister and F. L. Browne. Second edition (*Review*), 584

Cat: and the Lioness, Vaginal Smears and the Œstrous Cycle of the, Dr. H. Liche and Prof. K. Wodzicki, 245; Female, Neural Mechanism of Sexual Behaviour in the, Dr. J. P. Maes, 598

Catalase, Dr. R. Lemberg, M. Norrie and J. W. Legge, 551

Cataract, Inheritance of, M. C. Bourne and H. Grüneberg, 38

Cattle Fodder and Human Nutrition, with special reference to Biological Nitrogen Fixation, Prof. A. I. Virtanen (*Review*), 134

Celestine, Colour of, Dr. J. Newton Friend and T. P. Allchin 633

Cell: Surface, The Biology of the, Dr. E. E. Just; Dr. J. F. Danielli (*Review*), 879; The, and Protoplasm: symposium at Stanford University, Prof. C. V. Taylor, 884

Cellulose: Industry, with special reference to the Paper and Allied Industries, J. Grant, 217; Textile Industry, H. A. Thomas, 217

Cement and Concrete, R. Friedland (in Hebrew) (*Review*), 367

Cements, Solubility of, 294

Central: Nervous System: Integration in the (*Review*), 50; The Form and Functions of the, an Introduction to the Study of Nervous Diseases, Prof. F. Tilney and Prof. H. A. Riley. Third edition (*Review*), 50; Register: The, Section for Scientific Research, 625; Midwives Board, Annual Report of the, 975

Centromere, Crossing-over near the, K. Mather, 161

Cerambycidæ, Biology of the, C. F. C. Beeson and B. M. Bhatia, 120

Cercospora Leaf Spot Disease of Bananas, Dr. C. W. Wardlaw, 11

Ceylon, Forest Trees in, Check-Lists of, 664

Champignons, bons, Ce qu'il faut savoir pour manger les, G. Portevin (*Review*), 893

Charcoal Iron Industry, H. Gwyn Jones, 916

Charophyta, British Purbeck, Prof. T. Maxwell Harris (*Review*), 1077

Chasmogamic, Cleistogamic and, Flowers in Wild Violets as a Photoperiodic Response, Formation of, G. Borgstrom, 514

Chemical: Formulary, The, Editor-in-chief, H. Bennett. Vol. 4 (*Review*), 193; Thermodynamics, The Fundamentals of, Part 1: Elementary Theory and Electrochemistry, Dr. J. A. V. Butler. Third edition (*Review*), 584; Society, resignation of Prof. J. W. Cook of the honorary secretaryship; appointment of Prof. W. Wardlaw as his successor, 627; Engineering, A Practical Manual of, H. Tongue (*Review*), 727; Engineering, Some Aspects of (*Review*), 727; Calculations, Intermediate, Prof. J. R. Partington and Kathleen Stratton (*Review*), 740; Society, Advisory Research Council of the, 745; Club, Activities of the, 781; Analysis, Standard Methods of, Dr. W. W. Scott. Fifth edition, edited by Prof. N. H. Furman. 2 Vols. (*Review*), 803; Principles, A course of Study in, Prof. A. A. Noyes and Prof. M. S. Sherrill. Second edition (*Review*), 897; Warfare, Chemistry of, A. Marshall (*Review*), 996

Chemie, physikalischen, Kurzes Lehrbuch der, Prof. H. Ulich. Unter mitarbeit von Dr. K. Cruse (*Review*), 194

Chemistry: Crystal: An Introduction to, Dr. R. C. Evans (*Review*), 6; Dr. O. W. Stillwell (*Review*), 6; F. I. G. Rawlins (*Review*), 6; and Genetics, A. F. Blakeslee, 120; Annual Reports on the Progress of, for 1938. Vol. 35 (*Review*), 194; Technical, Trends of Progress in, 216; Organic: and Bio-, Prof. R. H. A. Plimmer. Sixth edition (*Review*), 268; Growing-points of, Prof. J. Read (*Review*), 349; Pharmaceutical: (*Review*), 402; Bentley and Driver's Text-Book of, Revised by Dr. J. E. Driver. Third edition (*Review*), 402; An Encyclopædia of (*Review*), 491; Applied, Thorpe's Dictionary of, Vol. 3: Chemical Calculations-Diffusion, Sir Jocelyn Thorpe and Dr. M. A. Whiteley. Fourth edition (*Review*), 491; Inorganic, A Higher School Certificate, Dr. E. J. Holmyard (*Review*), 584, Mellor's Modern Inorganic, revised and edited by Dr. G. D. Parkes in collaboration with Dr. J. W. Mellor (*Review*), 584; Inorganic: F. A. Philbrick (*Review*), 740; Factual Tests in (Post School Certificate Standard), F. A. Philbrick; Answers to Factual Tests in Inorganic Chemistry, F. A. Philbrick (*Review*), 897; Protein (*Review*), 923; Physical, New Technique in, Dr. H. W. Melville, 925; of the

Alkali and Alkaline Earth Metals (*Review*), 1064; Inorganic, Revision Notes in, to Higher School Certificate, E. P. Wilson and F. W. Ambler (*Review*), 1079
Chemotherapy, Recent Advances in, Dr. G. M. Findlay. Second edition (*Review*), 194
Cherries, Duke, Origin of the, K. Hruby, 757
Chick, Evocation in the, M. Abercrombie, 1091
Children with Delayed or Defective Speech: Motor-Kinesthetic Factors in their Training, Dr. Sara M. Stinchfield and Mrs. Edna Hill Young (*Review*), 744
China: Peasant Life in, a Field Study of Country Life in the Yangtze Valley, Dr. Hsiao-Tung Fei (*Review*), 267; Early Man in, Recent Researches on, I, 1054: North, Late Cenozoic History of, P. Teilhard de Chardin, 1054; Fossil Man in, Duration of Life in, Prof. H. Vallois, 1055; Early Man in, Recent Researches on, II, 1097
Chinese: Peasant, The (*Review*), 267; Order of the Brilliant Jade, conferment of the, on Dr. H. Chatley, 938
Chloral: Hydrate, Elimination of Administered, in the Urine as a test for Liver Function, Dr. B. Mukerji and R. Ghose, 112; Free, Blood Clearance of, in Normal and Liver-damaged Dogs, Dr. B. Mukerji and Dr. R. Ghose, 636
Chloronaphthalenes, Metabolism of, R. V. Cleary, J. Maier and G. H. Hitchings, 122
△3, 5-Cholestadiene from Cholesteryl Oleate and its possible bearing upon the Formation of Carcinogenic Substances in Heated Fats, Dr. H. Veldstra, 246
Cholinesterase and Electrolytes, Prof. B. Mendel, Dorothy Mundell and Frida Strelitz, 479
Chorthippus bicolor and *Ch. biguttatus*, Crossing of, H. Klingstedt, 161
Choukoutien, Upper Cave Industry of, W. C. Pei, 1097
Christianity and Morals, late Prof. E. Westermarck (*Review*), 173
Chromosome: Structure, Prof. R. R. Gates, 81; Gene and, Theory, Dr. H. J. Muller, 814
Chromosomes: Heterochromatic Regions of, D. Kostoff, 38; affected by X-Rays, Effect of Temperature on, K. Sax and E. V. Enzmann, 790; Abnormal, Genetical Analysis of, B. McClintock, 837
Chrysanthemum Midge, Control of the, 280
Ciliary and Muscular Movement, Calcium in, Dr. G. S. Carter, O. Gatty, Dr. J. H. Schulman and Dr. H. Walston, 980
Cinema, Sociological aspects of the, O. Bell, 520
Cirripedes, Parasitic, of the John Murray Expedition, K. A. Pyefinch, 601
City and Guilds of London Institute, conferment of fellowship on L. B. Atkinson, C. R. Fairey, E. Fawssett, Dr. L. F. Goodwin, Sir Follett Holt, Sir Gilbert T. Morgan, F. Handley Page and Sir Leonard Pearce, 242
Civil Engineers, Institution of, award of a Charles Hawksley prize to D. H. May and a grant of £50 to A. J. Francis, 29; formation of a Railway Engineering Section, 70
Civilization, The Future of, 489; The Prospects of, Sir Alfred Zimmern (*Review*), 1031
Civilizations: Ancient, The Collapse of, S. Casson, 404;
Cleistogamic and Chasmogamic Flowers in Wild Violets as a Photoperiodic Response, Formation of, G. Borgstrom, 514
Climate and Man, Dr. C. E. P. Brooks (*Review*), 1066
Clover, Red, Chlorophyll Deficiencies in, R. D. Williams, 253
Club-root, Control of, Margaret J. Smieton, 1053
Coal: Utilization of: Sir Evan Williams, 106; by Electricity, M. Anderson, 505; Bursting, A. Harvey, 872
Coals, Commercial, Analyses of, 790
Coenzymes I and II, Synthesis of, Drs. S. P. and R. W. Vilter and Prof. T. D. Spies, 943
Coffee Endosperm, Genetical Proof of the Existence of, C. A. Krug and A. Carvalho, 515
Cohnheim, Prof. Julius, centenary of the birth of, 105
Colchicine, Polyploidy induced by, and its Economic Possibilities, Dr. G. H. Bates, 315
College of Physicians of Philadelphia, award of the Alvarenga prize to Prof. H. Goldblatt, 375
Colonial: Office appointments, 110; 324; 665; 862; 1009; Policy, New Tendencies in, 240
Colonies and Raw Materials, H. D. Henderson (*Review*), 1031
Colour: in Theory and Practice, H. D. Murray and Dr. D. A. Spencer. Vol. 1: General Theory (*Review*), 227; The Science of, Dr. S. Clay (*Review*), 227
Comet: 1939*d*, Spectrum of, F. Hinderer, 254; Kamensky 558; Tuttle, Periodic, 558; Giacobini–Zinner, Discovery of, 748
Comets, Recent, 862
Complex Variable: The Theory and Use of the, an Introduction, S. L. Green (*Review*), 741
Composts: Seed and Potting, with special reference to Soil Sterilization, W. J. C. Lawrence and J. Newell (*Review*), 581
Compression Modulus, Differential Threshold for, Dr. G. W. Scott Blair and Miss F. M. V. Copper, 286
Computation and Trigonometry, H. J. Gay (*Review*), 585
Comte, Auguste, méthode et intuition chez, Dr. P. Ducassé (*Review*), 587
Concrete: Reinforced, Research, 716; 'Vibrated', R. F. Irving. 904
Consumer–Buyer, The, and the Market, Jessie V. Coles (*Review*), 195
Contraceptive Advice by Local Authorities, 149
Coolidge Tube Target, Extremely Bright Spots on, I. Koga and M. Tatibana; J. Forman, 511
Copper: Early, H. H. Coghlan, 484; Conductors, Origin of Defects in, J. E. Deering, 950 . Electro-deposition of, [1839], 990
Cornish Promontory Forts, 361
Correlation, Mathematical Theory of, Principles of the, A. A. Tschuprow. Translated by Dr. M. Kantorowitsch (*Review*), 799
Cosmetics, Trend of Progress in, H. S. Redgrove, 217
Cosmic: Radiation, Hard and Soft Component of, Directional Distribution of the, Dr. J. Barnóthy and Dr. M. Forró, 116; Ray: Particles, Heavy, at Jungfraujoch and Sea-level, Dr. W. Heitler, Dr. C. F. Powell and Dr. G. E. F. Fertel, 283; Ionization Bursts, Dr. H. Carmichael and Chang-Ning Chou, 325; Data, Dr. E. Hubble; Prof. H. N. Russell, 507; Rays at High Altitude, T. H. Johnson and J. G. Barry, 677; Ray Showers of Atmospheric Origin, Investigation of, using Two Cloud Chambers, Dr. A. C. B. Lovell and J. G. Wilson, 863; Machinery in an Electro-Magnetic Universe, Capt. H. A. Staples (*Review*), 900; Rays, Baade and Zwicky's theory of, and the Helium Content of Beryls, Dr. J. Read, 1046
Cotton: Mycorrhiza, Y. Sabet, 37; Industry, Reorganization of the, 409; Blackarm Resistance in, Genetics of, R. L. Knight and T. W. Clouston, 676; Multiple Allelomorphism in, R. A. Silow, 757; Sea-Island, Transplants of, Dr. Nazir Ahmad, 785
Country Life, Reminiscences of, J. G. Cornish. Edited by Dr. Vaughan Cornish (*Review*), 896
Cowper, Edward, at King's College, London, [1839], 720
Cowries, Geographical Distribution of the, 642
Cows, Dairy, Feeding of, J. Mackintosh, 257
Crab Nebula: The, A Probable Super-Nova, 874
Creatine as a Product of Methylation, C. J. Kelly and H. H. Beard, 162
Crepis, American Species of, E. B. Babcock and G. L. Stebbins, jun., 45
Crete: Santorin and, N. A. Critikos, 558; India and, J. G. Aravamuthan, 1095; Minoan, Volcanic Action in, S. Marinatos, 1095
Critical: and Co-operative Phenomena, 793; Phenomena in Gases, Prof. J. E. Lennard-Jones and Dr. A. F. Devonshire, 793
Cromer Forest Bed Implements, The, J. Reid Moir, 205
Crop Production, Sir John Russell, 217
Crotoxin, Prof. K. H. Slotta and H. Fraenkel-Conrat, 290

Crystallo-Chemical Analysis: The Barker Index at Oxford, Dr. M. W. Porter and R. C. Spiller, 298
Crystal Formation During Embedding of Plant Material in Paraffin Wax, Avoidance of, Dr. P. Brough, 250
Crystals, The Nature of, A. G. Ward (*Review*), 587
Cucumis Melo, Polyploid Cells in, C. D. Ervin, 946
Cushing, late Harvey, A Bibliography of the Writings of, Prepared on the Occasion of his Seventieth Birthday, April 8, 1939, by the Harvey Cushing Society (*Review*), 900
Cyanogenesis, Inheritance of, R. D. Williams, 837
Cyclo-Octatetrene, Structure of, C. D. Hurd and L. R. Drake, 448
Cyclotron: The, and Biological and Medical Research, 278; A new, 1087
Cypræidæ, Prodrome of a Monograph on Living, Drs. F. A. and M. Schilder, 642
Cyprus, Tuberculosis in, 663
Cytochrome, Oxidase in Tea Fermentation, J. Lamb and E. A. Houghton Roberts, 867
Cytogamy: A New Sexual Process in Joined Pairs of *Paramecium caudatum*, Dr. R. Wichterman, 123
Cytology, Dr. C. D. Darlington, 816

Daffodil, White Mould Disease of the, P. H. Gregory, 253
Daguerre's Discovery Described, [1839], 341
Dahlia Varieties, Origin of, A. J. Cobb, 209
Dalai Lama, Reincarnation of a, 779
Dalmatian Dogs, Preference of, for Particular Positions in Coach Running, and Inheritance of this Character, Prof. H. C. Trimble and C. E. Keeler, 671
Danubian Basin, The, C. A. Macartney, 1031
Daruma Volcano, Japan, H. Kuno, 485
Datura, Fifteen Years' Research on, A. F. Blakeslee and A. G. Avery, 253
Deafness, Causes of, Drs. W. Hughson, A. Ciocco and C. Palmer, 160
Decimal Classification, Universal, 147
Delinquency and Psychology, C. Mullins, 626
Demes: A Suggested New Terminology, J. S. L. Gilmour and Dr. J. W. Gregor, 333
Democracy: Educating for, Planned and Edited by J. I. Cohen and R. M. W. Travers (*Review*), 132; and Leadership, 221
Demotic Papyri in the British Museum, Catalogue of, Vol. 1: A Theban Archive of the Reign of Ptolemy I, Soter, Prof. S. R. K. Glanville (*Review*), 582
Dendochronology in the Eastern United States, Prof. C. J. Lyon, 1086
Deserts, Dr. G. Pickwell (*Review*), 460
Determinantal Loci, The Geometry of, Prof. T. G. Room (*Review*), 960
Deuteron: The Electric Quadrupole Moment of the, and the Field Theory of Nuclear Forces, Dr. C. Møller and Dr. L. Rosenfeld, 476; Bombardment of Silver, Dr. R. S. Krishnan and D. H. T. Grant; Dr. N. Feather, 547
Development Commission, Twenty-eighth Report, 49
Dew Ponds: A Study of (*Review*), 135; in Fable and Fact, A. J. Pugsley (*Review*), 135
Diabetogenic Anterior Pituitary Extracts, Histological Effects of, Prof. A. W. Ham and Dr. R. E. Haist, 835
Diacetone Dulcitols, Structures of, R. M. Hann, W. D. Maclay and C. S. Hudson, 757
Dice, Loaded, Prof. F. P. Worley, 712
Dielectric Polarisation in Liquids, On the Theory of, K. Zakrzewski and Dr. A. Piekara, 250
Diethylstilbœstrol in the Organism, Inactivation of, Prof. B. Zondek and Dr. F. Sulman, 596
Differentialgleichungen, Gewohnliche, Prof. G. Hoheisel (*Review*), 370
Differentiation, Growth and, Problems of, 561
Diffusion: Velocity and Molecular Weight, L. Friedman and P. G. Carpenter, 386; Processes, Study of, by Electrolysis with Microelectrodes, H. A. Laitinen and Prof. I. M. Kolthoff, 549
Dinosaurs, The Last of the, 335
Diode, The, As a Frequency-changer for Measurements at Ultra-high Frequencies, G. F. Gainsborough, 548
Dioscorea in the East, An Account of the Genus, Part 2: The Species which Twine to the Right; with Addenda to Part 1, and a Summary, Sir David Prain and I. H. Burkill (*Review*), 895
p-Diphenylbenzene, Structure of, and its Raman Spectrum, Prof. S. K. Mukerji and L. Singh, 382
Dipole Moment and Alkyl Chain Length, Dr. H. O. Jenkins, 667
Dipterous Larvæ and Wound Treatment, Dr. A. D. Imms, 516
Discovery, Saga of the, Comdr. L. C. Bernacchi (*Review*), 198
Discovery and Invention in War-time, 954
Disease: Classic Descriptions of, with Biographical Sketches of the Authors. Prof. R. H. Major. Second edition (*Review*), 195; Experimental Method in the Conquest of, Sir Edward Mellanby (Stephen Paget memorial lecture), 504; -Resistance, Inheritance of, L. T. Webster, 870
Dissociation Energy and Inter-Nuclear Distance, Inter-relation of, for Some Simple Di-Atoms in Ground States, Dr. C. H. Douglas Clark, 285
Documentation, International Co-ordination of, 559
Dogons: Jeux, M. Griaule (*Review*), 738; Masques, M. Griaule (*Review*), 738
Dolphin's Backbone, Adaptation in a, E. Lonnberg, 675
Double Star Orbits, Catalogue of, B. Ekenberg, 211
Dragonflies, A Reclassification of the, late Dr. R. J. Tillyard, 160
Drainage of Lands by Steam Power, [1839], 259
Drosophila: *melanogaster*: Chromosome Rearrangements in, B. P. Kaufmann and Ruth C. Bate, 121; Hairy Wing (*Hw*) in, M. Demerec and M. E. Hoover, 121; Chromosome Rearrangements in, B. P. Kaufmann, 385; Sterility in, S. Prabhu, 557; Development, Dr. C. H. Waddington, 561; Genetics of, Bibliography of the, Dr. H. J. Muller, 781; *pseudoobscura*, Wild, Genetic Differences in, T. Dobzhansky, 870; Development of Wings in, Dr. C. H. Waddington, 912
Drugs and Galenicals: Their Quantitative Analysis, Dr. D. C. Garratt (*Review*), 402
Dual Policy, The, Sir Arthur Salter (*Review*), 1031
Dublin, Demography of, 1043
Ducks, Game, Food of, A. C. Martin and F. M. Uhler, 1007
Du Fay, Charles François de Cisternay, Bicentenary of the Death of, 105
Dundee and District, Scientific Survey of, 438
Dunstan's Law, A. H. Nissan, 383
Durham University, conferment of honorary degrees on Sir Charles Peers and C. A. Linge, 875
Dust: Particles: Visibility of, Effect of Tube-length on the, with an Oil-immersion Objective, D. G. Beadle and H. S. Patterson, 327; F. E. J. Ockenden, 516; and Disease, Dr. A. Assémat, 662
Dutch Colonial Institute, work of the, 190
Dyeing with Coal-Tar Dyestuffs: The Principles Involved and the Methods Employed, C. M. Whittaker and C. C. Wilcock. Third edition (*Review*), 740
Dye-Wood, [1839], 720
Dynamics, Fluid, Modern Developments in. Edited by Dr. S. Goldstein. 2 Vols. (*Review*), 529
Dyson, Sir Frank, Mrs. Margaret Wilson, 869

Earth: The Central Core of the, Gutenberg and Richter, 210; Rotation of the, Rate of, Dr. H. Spencer Jones, 254; Architecture of the, Prof. R. A. Daly (*Review*), 403; The Rape of the, A World Survey of Soil Erosion, G. V. Jacks and R. O. Whyte (*Review*), 647; Tremor: near Ottawa, 748; in New England, 904
Earthquake: on the Gold Coast, 18; Insurance, E. Tillotson, 297; near the New Hebrides, 544; near Smyrna; other Recent Earthquakes, 589; in Bulgaria, 748; in Turkey, 938; Belgian, of June 11, 1938, O. Somville, 950; in the New Hebrides, 975; near Seattle, 1009; in New England, 1043

Earthquakes: in California, 66; Registered During February 1939, E. Peterschmitt, 81; During April 1939, 109; Registered at De Bilt During 1936, Dr. G. Van Dijk, 241; Long-wave Phase of, Stoneley, 254; During May 1939, 323; During June 1939, 567; and Crustal Structure near Japan, S. Yamaguti, 602; Recent, 780; Disastrous, January–June 1938, J. P. Rothé, 871; in Central America and Canada, 904; Registered at Kew During October 1939, 904; Registered at Kew, 1043

Earth's: Upper Atmosphere, Nitric Oxide in the, Prof. J. Kaplan, 152; Atmosphere, Evolution of the, Dr. H. Spencer Jones, 161; Green Mantle: Plant Science for the General Reader, Prof. S. Mangham (*Review*), 364; Crust: The, Its Fabric and Foundations, Prof. P. G. H. Boswell (*Review*), 403; in the East Indian Archipelago, Contributions to the Knowledge of the Chemical Composition of the, Dr. W. van Tongeren. Parts 1 and 2 (*Review*), 652; the Rare (*Review*), 959

East: Indian Rocks, Spectrographic Analysis of, Dr. J. Newton Friend (*Review*), 652; Indies, Oceanography of the (*Review*), 651

Ecological Glossary, An, Dr. J. R. Carpenter (*Review*), 1030

Economic: Co-ordination, Adviser on. Appointment of Lord Stamp as, 665; Self-Sufficiency, Prof. A. G. B. Fisher (*Review*), 1031

Economics, International, Planned, 683

Edinburgh University: J. Brough appointed lecturer in the zoology of vertebrates and J. E. G. Raymont lecturer in the zoology of invertebrates, 47; conferment of honorary doctorates on H. B. Butler, F. C. Nicholson, Prof. G. N. Watson and Prof. J. C. Webster, 87; conferment upon Dr. F. H. A. Marshall of an honorary doctorate, 219; W. C. Wilson appointed regius professor of surgery, 628

Education: in Democracy, The Function of (*Review*), 132; Modern, Teachers on, 186; A Californian School of, 281; in Germany, Dr. A. Lindegren, 321; Homemaking, Programs for Adults, 412: for Industry, Dr. A. P. M. Fleming, 433; Museums and, Earl De La Warr; J. Wilkie, 626; The Informative Content of, 759; and Industry, W. O. Lester Smith and others, 760; for Industry, Dr. A. P. M. Fleming, 852

Eelworm (*Heterodera marioni*), Oligodynamic Control of, J. W. H. Hovy, 672

Egg Storage, 545

Egypt, Recent Archæological Excavations in, 296

Egyptian Picture of the Sky, Dr. O. Neugebauer, 1042

Eiderdown Industry and Protection of Eider Ducks, 409

Elastic Waves, Dispersive, 'Packet Velocity' of, K. Sezawa and K. Kanai, 448

Electric: Discharge, Chemical Reaction in the, Dr. R. W. Lunt (*Review*), 93; Fuses, Testing of, J. A. M. van Liempt and J. A. de Vriend, 122; Tariffs, 'Time-of-Day', 126; Heating of Domestic Hot Water Supply, A. E. McKenzie, 280; Polarisation, Spontaneous, Specific Heat of a Substance Showing, Drs. J. and K. Mendelssohn, 595; Battery Vehicle, The, 627; Lighting in a Modern Store, 704; Discharge in Engineering Science, The, L. S. Harley and Dr. R. W. Lunt (*Review*), 769; Propulsion at Sea, A. C. Hardy, 780

Electrical: Units, Adjustment of, Dr. P. Vigoureux, 32; Interference in Flying, T. H. Kinman, 211; Progress in Poland, 341; Equipment of Buildings, 681; Grid in Great Britain, Johnstone Wright, 778; Resistance, Absolute Measurement of, Dr. H. R. Nettleton, 782; Supply Engineer in War-time, Function of the, J. W. Beauchamp, 914; Equipment of Ships, Regulation for the. Third edition, 936

Electricity: Industrial, Direct-Current Practice, Prof. W. H. Timbie. Second edition (*Review*), 368; Olfactory, 437; Dr. T. F. Wall (*Review*), 588; in Mining, D. J. Thomas, 937

Electro-Acoustics, Prof. E. Meyer (*Review*), 741

Electrochemistry of Gases and other Dielectrics, Prof. G. Glockler and Prof. S. C. Lind (*Review*), 93

Electrolytes: Cholinesterase and, Prof. B. Mendel, Dorothy Mundell and Frida Strelitz, 479; Strong, Activity Coefficients of, P. van Rysselberghe and S. Eisenberg, 1053

Electromagnetic Microbarographs, Observations with, Dr. H. Benioff and Dr. B. Gutenberg, 478

Electromagnetics: A Discussion of Fundamentals, Prof. A. O'Rahilly (*Review*), 91; Fundamental Concepts of, Dr. C. V. Drysdale (*Review*), 91

Electro-Magnetism as a Motive Power, [1839], 643

Electromechanical Transducer, An, J. J. Delvin, 39

Electron: -Microscope, The, and the Investigation of Viruses, von Borries and E. Ruska, and others, 40; Point Charge, A New Model of the, and of other Elementary Particles, Prof. E. C. G. Stueckelberg, 118; Optics: L. Jacob (*Review*), 401; O. Klemperer (*Review*), 401; Theoretical and Practical, J. M. Myers (*Review*), 401; Tubes, Theory and Applications of, Prof. H. J. Reich (*Review*), 401

Electronics, Fundamental, and Vacuum Tubes, Prof. A. L. Albert (*Review*), 401

Elektrischen Nachrichtentechnik, Vierpoltheorie der, Einführung in die, Prof. R. Feldtkeller (*Review*), 311

Elm, White Rot of the, W. H. Wilkins, 518

Embryology: Experimental, Dr. G. R. de Beer (*Review*), 493; Genetics and, Prof. C. Stern, 561

Empire Broadcasts on Scientific Topics, 239

Empires: Buried, The Earliest Civilizations of the Middle East, P. Carleton (*Review*), 893

Emulsions, Action of Copper Salts on, Stabilised by Sodium Oleate, A. R. Martin and R. N. Hermann, 479

Encirclement, J. L. Brierly (*Review*), 1031

Engineer, The, and the Steelmaker, D. Taylor, 793

Engineering Biography (*Review*), 690

Engineers: Training: in Management for, Importance of a, T. G. Rose, 218; of: 218; Dr. B. H. Knight, 673; the Writer of the Article, 674; Great, Prof. C. Matschoss. Translated by Dr. H. S. Hatfield (*Review*), 690; in War-time, Sir Clement Hindley, 825

England: South-East, Structure, Surface and Drainage in, S. W. Wooldridge and D. L. Linton, 121; and Wales, Quarterly Report of Births in, 976

Entomological Society of Southern Africa, *Journal* of the, Vol. 1, 108

Entomology, Medical, Dr. W. A. Riley and Dr. O. A. Johannsen. Second edition, 191

Environmental Conditions and Physical Characters, Prof. F. Wood Jones (*Review*), 177

Enzymes, Respiratory, University of Wisconsin Biochemists, under the direction of C. A. Elvehjem and P. W. Wilson (*Review*), 997

Equations, Theory of. Introduction to the, Prof. L. Weisner (*Review*), 370

Error, Law of, and the Combination of Observations, H. R. Hulme and L. S. T. Symms, 558

Ethics? Does Science Afford a Basis for, Prof. E. G. Conklin, 935

Ethyl: Alcohol, Pure, for Absorption Spectrophotometry, Dr. A. Clow and G. Pearson, 208; -Thioglucosides, The, and a New Monoacetoneglucose, Brigl, Gronemeier and Schultz, 680

Ethics in Modern Art, Marjorie Bowen (Conway Memorial Lecture) (*Review*), 1082

Eugenic Policy, Positive, Dr. C. G. Darwin (Galton lecture), 67

Europe, New, Science and the, 919

European Order and World Order, 934; 948

Europium, Salts of, H. N. McCoy, 791

Eutheria: The Ancestors of the, Dr. A. A. Abbie, 523; Prof. W. E. Le Gros Clark, 600

Evacuation: Sociological Aspects of, 529; War-time, Social Problems of, 1025

Everest: The Last Thousand Feet on, Possible Bacterial Factor, Dr. J. A. Campbell, 113; Mount, Scientific Research in the Region of, Dr. R. Greene, 158

Evolution: Perspectives in, Prof. J. Ritchie, 428; 534; and Systematics, Genetics in Relation to, Dr. W. B. Turrill, 822

Excavations: at Brundon, Suffolk, J. Reid Moir; A. T. Hopwood, 556; at Mas d'Azil, France, Marthe and Saint-Just Péquart, 556
Eye Colour, Bacterial Synthesis of an, E. L. Tatum, 1017
Ezion-Geber, Excavations at, Dr. N. Glueck, 278

Factories and the Black-out, H. W. Cremer and others, 1023; Chief Inspector of, Report of the, for 1938, 486
Factory without Windows, 322
Fan Memorial Institute of Biology, Bulletin of the, July–Aug. 1938, 69
Farm: Electrification, A. G. H. Dent, 663; Forestry, W. A. Ross and W. R. Mattoon, 828
Farmer's Position, The, and the Scientific Workers' Programme, Sir Thomas Middleton, 434
Fauna of the Seaside, The (*Review*), 997
Fern: Common Male, in Britain, Cytology of the, Dr. I. Manton, 291; Vegetative Propagation of a, E. E. Kemp, 294
Ferromagnetism: The Development of a General-Equation to Magnetism, Dr. J. R. Ashworth (*Review*), 399
Fibre-Follicle Terminology in the Mammalia, Dr. A. B. Wildman and H. B. Carter, 783
Field Archæology in War-Time, 589
Film: Reactions as a New Approach to Biology, Prof. E. K. Rideal, 427; Areas, Measuring, Comparison of the Adsorption, Electrolytic, and Interference Methods of, Prof. F. H. Constable, 630
Films: Scientific, List of, 190; Built-up, Thickness of, Dr. G. I. Jenkins and A. Norris, 441; Reactions as a New Approach to Biology, Prof. E. K. Rideal, 693
Finland, Invasion of, 971
Fireclay, Peaty, Occurrence of Wax-like Substances in, V. L. Bosazza, 835
Fire-Fly 'Spinthariscope', Prof. R. W. Wood, 381
Firemen, Vocational Training for, 361
First Aid Posts and Workers, 661
Fish Movements and Fishpasses, Dr. P. Nemenyi (*Review*), 567
Fisheries Research in Australia, Sir David Rivett, 312
Fishery: Statistics, Sir D'Arcy W. Thompson, 445; Research in Scotland, 487
Fishes: Scales of, [1839], 169; Some Early Ganoid, Sir A. Smith Woodward (*Review*), 615; Deep-Sea, of Bermuda, Dr. W. Beebe and Jocelyn Crane, 638; Palæozoic, J. A. Moy-Thomas (*Review*), 1078
Flavin-Adenine-Dinucleotide in Tissues of Rats on Diet Deficient in Flavin, Dr. S. Ochoa and R. J. Rossiter, 787
Flavoprotein from Liver, Isolation of a Catalytically Active, V. Subrahmanyan, Dr. D. E. Green and A. H. Gordon, 1016
Fleas, Embryology of, E. L. Kessel, 160
Flocculi, Small Chromospheric, Motion Pictures of, R. R. McMath, 336
Flora: of Britain, Concise, for the Use of Schools, with Explanatory Illustrations and Keys to Identification, F. K. Makins (*Review*), 365; of Devon: Phanerogams, Vascular Cryptograms, Charophyta, Edited by Rev. W. K. Martin and G. T. Fraser, with the Assistance of Rev. T. Stephenson and F. M. Day (*Review*), 583
Floral Morphology: A New Outlook with Special Reference to the Interpretation of the Gynæceum, Miss E. R. Saunders. Vol. 2 (*Review*), 350
Flour Beetle *Tribolium confusum* Duv., A Peculiar Phenomenon Observed in Larval Populations of the, Prof. J. Stanley, 753
Flower, Morphology of the, Dr. W. B. Turrill (*Review*), 350
Fluid Dynamics, Modern Developments in, Edited by Dr. S. Goldstein. 2 Vols. (*Review*), 529
Fluidity and Temperature, E. C. Bingham and S. D. Stookey, 448
Fluorides, Complex, Structure of, J. L. Hoard and W. B. Vincent, 984
Fluorine: from Potable Waters, Removal of, Dr. P. K. van der Merwe, 668; with Carbon, Reaction of, J. H. Simons and L. P. Block, 947
Fluorite in Somerset, A New British Locality for, A. W. G. Kingsbury, 1013
Fluorosis in India and in England, Distribution of, Dr. D. C. Wilson, 155
Flying, The Future of, Dr. H. E. Wimperis, 480; 538
Fog in the Netherlands, Dr. C. Braak, 947
Folsom Man: Further Investigation in Colorado, Dr. F. H. H. Roberts, jun., 902
Food: The Englishman's, A History of Five Centuries of English Diet, Prof. J. C. Drummond and Anne Wilbraham (*Review*), 264; Production in War-Time; Constitution of an Advisory Panel, 580; Commercial Irradiation of, 746
Foods: and Food Products, The Chemical Analysis of, Dr. M. B. Jacobs (*Review*), 194; The Structure and Composition of, Dr. A. L. Winton and Dr. Kate Barber Winton. Vol. 4 (*Review*), 366
Foot-and-Mouth Disease Research Committee, Dr. I. Galloway appointed scientific superintendent of research at the Pirbright Research Station of the, 705
Forbes, J. D.: Travels of, in 1839, 259; Baden Powell and Melloni [1839], 1058
Foreign Politics: Generalized, A Study in Group Psychology, Dr. L. F. Richardson (*Review*), 692
Forensic Science Laboratory, New, 259
Forest Administration, The Colonies and, Prof. E. P. Stebbing, 949
Forestry: in India (*Review*), 494; American, An Introduction to, Prof. S. W. Allen (*Review*), 614; An Outline of, T. Thomson and M. R. K. Jerram (*Review*), 614; Introductory (*Review*), 614; Commission, Nineteenth Annual Report of the, 761; *Abstracts*, 780
Forests, The Nation's, W. A. Du Puy (*Review*), 614
Form and Causality in Early Development, Prof. A. M. Dalcq (*Review*), 493
Forsythia, A Bacterial Disease of, Dr. G. Metcalfe, 1050
Forty Acres and Steel Mules, H. C. Nixon (*Review*), 586
Fossil: Fishes of the Yorkshire Coalfields, [1839], 876; Bones, Markings on, Pei Wen-Chung, 1017
Fossils from the London Clay [1839], 1024
Foundations and Earth Pressures, C. Hyde Wollaston (*Review*), 898
Founders Company Fellowship, award of the, to E. J. Ludlow, 242
Four-Terminal Networks (*Review*), 311
Fox Indians: Ethnography of the, late Dr. W. Jones, Edited by Margaret Welpley Fisher, 914; Tribal Origins and Culture Among the, 914; Sacred Feasts of the, 951
French: Association for the Advancement of Science: Liège Meeting; Prof. Pieron elected president of the 1940 meeting, 449; Academy, award of the Grand Prix Prince Albert I de Monaco to J. Lefèvre, 474
Freshwater Biology, Research in, 590
Fruit: Breeding in the U.S.A., M. A. Blake, 209; Flies of China, Y. Zia, 209; Juices, Value of, 590; Growing, Science and, 663; and Hops: Diseases of, Dr. H. Wormald (*Review*), 687; Pathological Problems of, D. E. Green (*Review*), 687
Fuel: Powdered, Progress and Prospects, 774; Industry in Great Britain, Col. W. A. Bristow, 825; House, Economizing on, E. S. Draper, 1041
Fuels, Home-produced, Sir Harold Hartley appointed honorary adviser on the development of, to the Secretary for Mines, 1088
Fuller, Anna, Fund of New Haven, Conn., award of the prize of the, to Prof. E. Kennaway, Prof. J. W. Cook, Dr. C. L. Hewett, Dr. I. Hieger and Dr. W. Mayneord, 150
Fulmar (*Fulmarus glacialis*), Distribution of the Colour Phases of the, J. Fisher, 941
Functions, The Theory of, Prof. E. C. Titchmarsh. Second edition (*Review*), 898

Fungal Hyphæ, Vacuolar Strain in, S. R. Bose, 80
Fungi: and Scale Insects, Symbiosis between, Prof. A. H. R. Buller (*Review*), 531; Entomogenous, T. Petch, 557
Fungicides, H. Martin, 217
Fur-trade in Northern Manchuria, W. N. Schernakow, 936

Galactose-1-Phosphoric Acid in Galactose Metabolism. Dr. H. W. Kosterlitz, 635
Gallium, Oxides and Hydroxide of, A. W. Laubengayer and H. R. Engle, 162
Gamma-Rays, Emission of, Resonance Capture of Slow Neutrons and, I. Nonaka, 831
Gannet, New Breeding Place of, Rev. J. M. McWilliam and Lord David Stuart, 675
Garden Plants, The Genetics of, M. B. Crane and W. J. C. Lawrence. Second edition (*Review*), 94
Garner Principle of Co-operative Activation, The, Prof. F. G. Donnan, 446
Gas: Industry in Great Britain, The, Prof. J. W. Cobb, 10; Reactions, Experimental Methods in, Dr. A. Farkas and Dr. H. W. Melville (*Review*), 268; Research Board, Sir David Milne-Watson elected president of the, 375; Producers for Motor-Cars, 855; Mask, An Early, 1040
Gaseous Electrical Conductors, Prof. E. L. E. Wheatcroft (*Review*), 769
Gases: Rare, Manufacture of, H. C. A. Holleman, 241; The Manipulation of (*Review*), 268; Critical Phenomena in, Prof. J. E. Lennard-Jones and Dr. A. F. Devonshire, 793; Non-Uniform, The Mathematical Theory of, An Account of the Kinetic Theory of Viscosity, Thermal Conduction, and Diffusion in Gases, Prof. S. Chapman and Dr. T. G. Cowling (*Review*), 993
Geiger Counter, Time Lags in a, A Determination of the Half-value Periods of Radium C' and Thorium C', with a Note on, J. V. Dunworth, 152
Gems and Gem Materials, Prof. E. H. Kraus and Prof. C. B. Slawson. Third edition (*Review*), 372
Gene and Chromosome Theory, Dr. H. J. Muller, 814
General Analysis, R. W. Barnard, 295
Genetic Systems: Come About, How, Dr. H. J. Muller (*Review*), 648; The Evolution of, Dr. C. D. Darlington (*Review*), 648
Genetica, Elementi di, G. Montalenti (*Review*), 364
Genetical: Aspects of Growth, Normal and Abnormal, Dr. A. Haddow, 823; Symbolism, Standardizing, 935
Genetics: "Modern", Introduction to, Prof. J. B. S. Haldane, Dr. J. S. Huxley, and Dr. H. J. Muller, 78; Dr. F. W. Sansome, 79; in the Garden (*Review*), 94; of Man, Prof. J. B. S. Haldane and U. Philp, 557; of the Rex Mouse, Prof. F. A. E. Crew and C. Auerbach, 557; and Embryology, Prof. C. Stern, 561; The Seventh International Congress of, 813; Physiological, Dr. C. H. Waddington, 817; Animal Breeding in the Light of, Dr. J. E. Nicholls, 818; Plant Breeding in the Light of, Dr. K. Mather, 820; Human, Prof. R. R. Gates, 821; in Relation to Evolution and Systematics, Dr. W. B. Turrill, 822; A Synopsis of, Dr. P. C. Koller (*Review*), 1067; An Introduction to, Prof. A. H. Sturtevant and Prof. G. W. Beadle (*Review*), 1067
Geodesy and Geophysics, International Union of, Prof. S. Chapman, 717
Geographical Region, The Natural, A. Stevens, 653
Geography, Method in, A. Stevens, 429
Geological: Time-Scale, Kinematical Relativity and the Dr. G. J. Whitrow, 706; Society [1839], 796; Society of London, Awards of the, to H. Woods, Prof. A. Holmes and Prof. H. L. Hawkins, 1044
Geology and Allied Sciences: A Thesaurus and a Co-ordination of English and German Specific and General Terms, W. Huebner. Part 1: German-English (*Review*), 368;
Geometry: Drawing-Board, 101 Problems in, Prof. F. G. Higbee (*Review*), 369; for Schools, A New, C. V. Durell (*Review*), 585
Geophysics, Geodesy and, International Union of, Prof. S. Chapman, 717
Geothermic: Power in Italy, 218; Generating Plant, A, 747
German: Culture in Prague, 778; -English Science Dictionary: For Students in the Agricultural, Biological and Physical Sciences, Prof. L. de Vries and others (*Review*), 900
Germanization and the University of Prague, 892
Germany: Education in, Dr. A. Lindegren, 321; Politics and Academic Qualifications in, 860; Marriages and Births in; 1010 Tuberculosis Mortality in, 1088
Germany's Oil Supplies, Dr. A. J. V. Underwood, 901
Giacobinid Meteors in 1939 and 1940? Dr. Fletcher Watson, 482
Gilbert, Davies, F.R.S., 1769–1839 [1839], 1058
Glaciers, Structure of, M. F. Perutz and G. Seligman, 757
Glossina morsitans, Physiology and Behaviour of, R. W. Jack, 714
Gloucester Museum, The, 411
Glutamic Acid: of Tumour Proteins, The, Prof. A. C. Chibnall, M. W. Rees, G. R. Tristram, E. F. Williams, and Dr. E. Boyland, 71; Prof. F. Kogl and Dr. H. Erxleben, 111; as a Hydrogen Carrier in Animal Tissues. Dr. H. A. Krebs and Dr. P. P. Cohen, 513;
Glutamine, Influence of, on the Growth of *Streptococcus hæmolyticus*, M. Landy, 512
Glycine: Crystal Structure of, G. Albrecht and R. B. Corey, 40; Condensation of the Hexapeptide Ester of, into the 96- and Higher (3×2^n) Peptide Esters, Prof. E. Pacsu, 551
Glycogen in the Liver, Formation and Breakdown of, P. Ostern and Dr. E. Holmes, 34
Gmelins Handbuch der anorganischen Chemie. Achte Auflage. System-Nummer 63: Ruthenium (*Review*), 897; Achte auflage. System-Nummer 39, Lief 1 (*Review*), 959; System-Nummer 22: Kalium, Lief 4: Verbindungen bis Kaliumacetat. System-Nummer 22: Kalium, Lief 5: Verbindung bis Kalium und Wismut; System-Nummer 24: Rubidium; System-Nummer 25: Caesium, Lief 1: Vorkommen, Darstellung und Eigenschaften des Metalls; System-Nummer 25: Caesium, mit einem Anhang uber Ekacaesium, Lief 2: Verbindungen des Caesiums, Ekacaesium; System-Nummer 27: Magnesium, Teil B, Lief 1: Verbindungen bis Magnesium und Jod; System-Nummer 27: Magnesium, Teil B, Lief 2: Verbindungen bis Magnesiumcarbonat; System-Nummer 27: Magnesium, Teil B, Lief 3: Verbindungen bis Magnesium and Wismut (*Review*), 1065
Goethe: medal for Art and Science, award of the, to Prof. T. Vahlen, 242; prize for Art and Science, award of the, to Prof. E. Fischer, 324; medal for Art and Science, award of the, to Prof. A. Schmidt and Dr. K. Frik, 508
Golden Gate Bridge, San Francisco, C. E. Paine, 146
Goose Lake Siderite, Prof. F. C. Leonard, 913
Gould, Schomburgk and, Travels of, [1839], 606
Government Laboratory, Work of the, for the Year Ending March 31, 1939, 663
Graham Land (*Review*), 54
Grain Weevil, Effects of γ-Radiation on the, An Experiment on the, L. G. Grimmett and G. V. B. Herford, 939
Granodiorite, Melting of, by Andesite, E. S. Larsen and G. Switzer, 676
'Granosan', Effect of the Fungicide, on A Typical Growth and Chromosome Doubling in Plants, Prof. D. Kostoff, 334
Graphite, Electrical Conductivity of, Large Anisotropy of the, Prof. K. S. Krishnan and N. Ganguli, 667
Grasping Movement in Man, Origin of the, Prof. D. Hooker, 1052
Grass: Leviathan from East Africa, A, Dr. I. B. Pole Evans, 34; Drying, E. J. Roberts, 545
Grassland and Forage Crops in the United States, 915
Gravitational Constant, Instability of the Mesotron and the, Prof. P. M. S. Blackett, 30

Great Britain, Laying the Keel of the, [1839], 127
Great Britain: The Littoral Fauna of, A Handbook for Collectors, Dr. N. B. Eales (*Review*), 997
Greek: Measures, Ancient, and Athletic Records, E. Kalfarentzos, 360; Bronze Coins, Ancient, Composition of, E. R. Caley, 1096
Greenkeeping Research, Board of, Report for 1938, 627
Greenockite in the Mendips, Occurrence of, A. W. G. Kingsbury and Dr. J. Newton Friend, 1013
Gregory, James: Tercentenary Memorial Volume, Edited by Prof. H. W. Turnbull (*Review*), 1062; (1638–1675), Prof. H. C. Plummer (*Review*), 1062
Grenoble, University of, sixth centenary of the, Prof. P. Vaillant, 42
Grid System, The, 190
Ground Vibrations Near Dynamite Blasts, L. Don Leet, 791
Growth: and Differentiation, Problems of, 561; Normal and Abnormal, Genetical Aspects of, Dr. A. Haddow, 823; Stimulating Effects of Extracts of Normal Adult Tissues and Tumours, Dr. R. S. Hoffman, Dr. E. Tenenbaum and Dr. L. Doljanski, 1092

Hæmocyanin Molecule, Dissociation of the, S. Brohult and S. Claesson, 111
Hair-Dyes and Hair-Dyeing Chemistry and Technique, H. Stanley Redgrove and the late G. A. Foan. New edition completely revised by H. Stanley Redgrove and J. Bari-Woollss (*Review*), 740
Harvard University, Physics Research at, 294
Hawaiian Bivalves, W. H. Dall, P. Bartsch, and H. A. Rehder, 484
Health: Perfect, The Leader to, Dr. E. F. Armstrong (*Review*), 264; Services, Control of, 300; The Building of a Nation's, Sir George Newman (*Review*), 345; and Safety in Industry, 486; Ministry of, Twentieth Annual Report of the, 678; Public, in Great Britain, 678
Hearing: its Psychology and Physiology, Dr. S. S. Stevens and Dr. H. Davis (*Review*), 570; Theories of, Prof. H. Hartridge (*Review*), 570
Heat: and Thermodynamics, Prof. M. W. Zemansky (*Review*), 196; Textbook of, Dr. R. W. Stewart and Dr. J. Satterly. Revised by C. T. Archer. Second edition (*Review*), 374; in Liquids, Propagation of, [1839], 488; Entropy Diagram for Steam, The 1939, Plotted from the 1939 Callendar Steam Tables, based on Research by Prof. A. C. Egerton and G. S. Callendar (*Review*), 1069
Hebrew University, Jerusalem, Progress of the, 187
Helium: Gas, Adsorption of, on Active Charcoal between 4·2° and 1·78° K., Prof. A. van Itterbeek, W. van Dingenen and J. Borghs, 249; II: Heat Flow in, Forces Associated with, Dr. J. F. Allen and Dr. J. Reekie, 475; Liquid, Effect of an Excitation Energy on the Specific Heat of, and its Relation to the Exchange Effect in a Non-Ideal Bose-Einstein Gas, Dr. A. Michels, Dr. A. Bijl and Dr. J. de Boer, 594; Ratios of Igneous Rocks, Evans, Goodman, Keevil, Lane and Urry, 677; -Neon Content of Sea Water, N. W. Rakestraw, C. E. Herrick and W. D. Urry, 838
(*Helix pomatia*), The Snail, Chitin Content of the Mandible of, Dr. G. Tóth and L. Zechmeister, 1049
Herd, Instincts of the, Dr. W. T. Calman (*Review*), 5
'Hermanation', H. Weltzel, 789
Hibernation, Artificial, Dr. P. Suomalainen, 443
High Resistance Resistors, 148
Himalayan Village: An Account of the Lepchas of Sikkim, G. Gorer (*Review*), 96
Histamine in Biological Extracts, Determination of, M. R. e Silva, 252
Histologischen Methodik, Physikochemische Grundlagen der, Prof. K. Zeiger (*Review*), 1079
Hitler's, Herr, Self-Disclosure in "Mein Kampf", R. C. K. Ensor (*Review*), 1031
Holland, Average Duration of Life in, 110
Holz als Rohstoff: Das, Seine Entstehung, stoffliche Beschaffenheit und chemische Verwertung, Dr. R. Trendelenburg (*Review*), 924
Homogeneous Fluids, The Flow of, through Porous Media, Dr. M. Muskat. With an Introductory Chapter by R. D. Wyckoff (*Review*), 197
Homo sapiens: The Fate of, An Unemotional Statement of the Things that are Happening to Him Now, and of the Immediate Possibilities Confronting Him, H. G. Wells (*Review*), 397
Honey Bee, Choice of Water by the, C. G. Butler, 984
Hops: Fruit and, Diseases of, Dr. H. Wormald (*Review*), 687; Fruit and, Pathological Problems of (*Review*), 687
Hormone Standards, New International, 934
Hormones, Intercellular, Production of, by Mechanical Injury, Prof. J. R. Loofbourow, E. S. Cook, Sister Cecelia Marie Dwyer and Sister Mary Jane Hart, 553
Hormonforschung, Methodik der, Dr. C. Bomskov. Band 2 (*Review*), 192
Hospital Schools in the United States, 975
Host and Parasite in Higher Plants, Union between, Schumacher and Halbsguth, 258
House-Sparrow in Canada, R. L. Weaver, 983
Housing, Social and Technical Aspects of, 1040; Urban and Rural, M. B. Holger, 1041
Human: -Birth Weights, H. P. Donald, 38; Relations, A Study of, Dr. K. Mather (*Review*), 310; Uterine Gland Cell, Cytology of the, Prof. J. B. Gatenby and Miss Olive E. Aykroyd, 331; Anatomy, Introducing, Prof. F. Wood Jones (*Review*), 351; Ability, The Factorial Analysis of, Prof. G. H. Thomson (*Review*), 532; Genetics, Prof. R. R. Gates, 821; Personality and its Survival after Bodily Death, late F. W. H. Myers. 2 Vols. (*Review*), 1027; Origins and Taboo, J. C. McKerrow, 1048
Humoral Immunity among Plants, A. F. Parker-Rhodes, 907
Humus: Origin, Chemical Composition and Importance in Nature, Prof. S. A. Waksman. Second edition, (*Review*), 893
Hyæna, Spotted, Reproduction of the, L. H. Matthews, 983
Hybrid, An Inter-Generic, B. O. Mulligan, 160
Hybridization, Increased Mutation Due to, A. H. Sturtevant, 912
Hydraulics: for Engineers and Engineering Students, Prof. F. C. Lea. Sixth edition (*Review*), 584
Hydrogen: and Oxygen Sensitized by Nitrogen Peroxide, Reaction between, Prof. R. G. W. Norrish and F. S. Dainton, 30; Atomic Weight of, J. A. Swartout and M. Dole, 485; Peroxide: Decomposition of, by Catalase, F. H. Johnson and Dr. K. L. van Schouwenburg, 634; Mechanism of Decomposition of, by Catalase, Prof. D. Keilin and Dr. E. F. Hartree, 787; Decomposition of, by Catalase, Dr. J. Weiss and Dr. H. Weil-Malherbe, 866; Showers in the Auroral Region, Prof. L. Vegard, 1089; Peroxide, Decomposition of, by Catalase, Prof. D. Keilin and Dr. E. F. Hartree, 1091
Hypertension: The Substance Causing Renal Hypertension, J. M. Muñoz, E. Braun-Menéndez, J. C. Fasciolo and L. F. Leloir, 980

Ice Age in India and Associated Human Cultures, Studies on the, Dr. H. de Terra and T. T. Paterson (*Review*), 738
Iceland Papers, Vol. 1: Scientific Results of Cambridge Expeditions to Iceland, 1932–38 (*Review*), 373
Identity, Evidence of, K. Richmond (*Review*), 372
Igneous Action, Metamorphism and, Prof. H. H. Read, 729; Prof. H. H. Read, 772
'*Illænus*' *proles* var. *shelvensis* Whittard, Cranidial Muscle Scars of, Dr. A. Lamont, 206
Illegitimate Child, Legal Position of the, 322
Illumination, Progress of, 604
Imperial Cancer Research Fund: New Laboratories, 16; 41

Incentives and Contentment; a Study made in a British Factory, Patricia Hall and H. W. Locke (*Review*), 1082

Indene, Toxicity of, G. R. Cameron and Cecile R. Doniger, 1095

India: Greater, Forthcoming International Exhibition of the Art of, 20; Imperial Veterinary Research Institute of the Government of, Prof. F. C. Minett appointed director of the, 105; Higher Education in, Objectives of, 148; Pasteur Institute of, Kasauli, Annual Report for 1936, Dr. R. O. A. Smith, 148; Southern, Pasteur Institute of, Annual Report for 1937, Lt.-Col. K. R. K. Iyengar, 148; Public Health Statistics of, 281; Aboriginal Races of, B. S. Guha, 293; Hygiene and Public Health in, 362; Health of the Army in, During 1937, 506; Government of, Industrial Research Bureau, Report for the Year 1938–39, 625; Anthropological Studies in, 721; and Burma, Common Water and Marsh Plants of, 1936, Hand-Book of the, K. Biswas and C. C. Calder (*Review*), 727; New Anthropological Periodical in, 745; Archæological Survey of, A Report on the Work of the, Sir Leonard Woolley, 758; British, Health in, During 1937, 974; National Institute of Sciences of, election of fellows, 976; and Crete, J. G. Aravamuthan, 1095

Indian: *Bee Journal*, No. 1, 109; Association for the Cultivation of Science, Annual Report for 1938, 412; Silviculture, Part 1: General Silviculture, H. G. Champion; Part 2· Silvicultural Systems, Sir Gerald Trevor (*Review*), 494; Medical Institutes, Work of, 506; *Journal of Entomology*, Parts 1 and 2, 780; Archæology and Indian Problems, Sir Leonard Woolley (Birdwood Memorial Lecture), 1006; Medical Review, An, Major-Genl. Bradfield, 1087

Industrial: Health Research Board, Dr. D. Hunter and H. E. Clay appointed members of the, 242; 375; Councils, Joint, 319; Health Research Board, Nineteenth Annual Report, 1008

Industry: and Society, Science, 1; Health and Safety in, 486; and Labour, The World of, 1939, J. E. Winant, 686; Education: and, W. O. Lester Smith and others, 760; for, Dr. A. P. M. Fleming, 852

Infant Brain, Respiratory Metabolism of, H. E. Himwich, Z. Baker and J. E. Fazekas, 38

Influenza, Periodicity of, D. Webster, 756

Information, Ministry of, 700; 745

Ingénieurs Civils de France, Société des, presentation of the gold medal of the, to W. T. Halcrow, 70

Innes, John, Horticultural Institution, Twenty-ninth Annual Report of the, 68

Inorganic: Esters, Mechanism of Hydrolysis of, J. B. M. Herbert and E. Blumenthal, 248; Compounds, Complex, Stereochemistry of, J. C. Bailar and J. P. McReynolds, 1096

In Principio erat Verbum (*Review*), 1030

Insect: Size and Temperature, Dr. W. H. Golightly and Dr. Ll. Lloyd, 155; Legion, The, Dr. M. Burr (*Review*), 789; Physiology, The Principles of, Dr. V. B. Wigglesworth (*Review*), 800

Insecticides: J. T. Martin and F. Tattersfield, 217; Toxicity of Certain, G. R. Cameron and Cecile R. Doniger, 790

Insects: Collected in Traps at Rothamsted Experimental Station, Dr. C. B. Williams, 85; in Aircraft, Dr. F. G. S. Whitfield, 158; Col. F. P. Mackie, 250; in the Upper Air, Dr. A. D. Imms, 406; Physiology of, Dr. A. D. Imms (*Review*), 800

Institute of Medical and Veterinary Science, Adelaide, first annual report of the, 1088

Instruments in Science and Industry, R. S. Whipple, 461

Insulin Crystals, Wet, X-Ray Measurements on, Dr. Dorothy Crowfoot and D. Riley, 1011

Intensive Cultivation, History of, R. J. G. Hopp, 1086

Intercellular Wound Hormones, Local Growths in Animals Produced by Injection of, Prof. J. R. Loofbourow, A. A. Cueto, D. Whalen and Sister Mary Michaella Lane, 939

Interfacial Tension Curves, 'Breaks' in, C. C. Addison, 249

Internal Strains in Solids, Conference on, 165

International: Geological Congress, 1940, Arrangements for the, 149; Congress of Americanists in Mexico City, 319; Seismological Summary, July, August and September 1938, 474; Genetical Congress, Seventh, Prof. F. A. E. Crew, 496; Co-ordination of Documentation, 559; Society of Leather Trades' Chemists, election of Prof. P. Chambard as president, 603; Congress of Genetics, The Seventh, 813; Economics, Planned, 683; Union of Geodesy and Geophysics, Prof. S. Chapman, 717; Cancer Congress, Third, Prof. F. C. Wood, 839; Seismological Summary, Oct., Nov. and Dec. 1938, 903; Society of Medical Hydrology, Dr. J. Barnes Burt elected interim chairman of council, 1087

Invention, Discovery and, in War-time, 954

Inventions and Patents in Great Britain, 641

Iodine, Spark Spectrum of, Hyperfine Structure in the, Dr. S. Tolansky, 754

Ionization, Region F_2, throughout the Year, Characteristic Variation of, Prof. E. V. Appleton, 151

Ions: Electrons and Ionizing Radiations, Prof. J. A. Crowther, Seventh edition (*Review*), 374; Mercuric Halide Complex, A. B. Garrett, 1018

Iranian Petroleum, A Solid Naphthenic Acid from, Dr. T. Kennedy, 832

Iraq, Electrical Development in, W. H. Peters, 605

Iris Bulbs, Hot Water Treatment of, W. Buddin, 716

Iron Smelting: in Britain, Transition from Charcoal to Coke in, 916; in India, [1839], 952

Islamic Decorative Technique, Early, B. Gray, 912

Isomers, Short-Chain Interfacial Activity of, Dr. C. C. Addison, 783

*o-Iso*propenyl-phenols, Structure of the Dimeric Forms of, Wilson Baker and D. M. Besly, 865

Isotope Separation, New Prospects in, Prof. H. S. Taylor, 8

Italy: Geothermic Power in, 218; Order of Commendatore of the Crown of, conferment of the, on Prof. J. R. D'Aunoy, 665

Jamaica: Biological Expedition to, 17; Cambridge University Expedition to, Dr. V. J. Chapman, 964

Japan: National Research Council of, Report, Volume 2, No. 7, 149; The Population of, 508; National Research Council of, Report of the, 1008

Japanese Earthquake Research Institute, Prof. K. Terazawa appointed director of the, 628

Jardine's, Sir William, "British Salmonidæ", [1839], 682

Jena, Society of Medicine and Natural History of, presentation of the bronze memorial medal to Prof. R. Spanner, 29; Prof. O. Grossern awarded the silver medal of the, 199

Jenner and Napoleon, Dr. J. A. Nixon, 278

Jewish Hospital, Cincinnati, May Institute for Medical Research of the, Dr. A. Froehlich appointed pharmacologist to the, 976

Johannesburg Municipal Bus and Tram Sheds, 704

Johns Hopkins University School of Medicine, grants to the, by the Rockefeller Foundation, 749

Jungle Yellow Fever and other Diseases, 790

Jupiter: Planet, Rapidly Moving Spots on the, 748; The Great Red Spot on, B. M. Peek, 987

Jupiter's Cloud Forms, Chemistry of the Coloration in, R. Wildt, 602

Juvenile Delinquency, Dr. Rhodes; C. P. Hill; J. H. Bagot, 703

Kala-Azar, The Antimony Treatment of, Sir Leonard Rogers, 1003

Kansas, Lower Permian Insects of, F. M. Carpenter, 641

Kantian Philosophy of Space, The, Prof. C. R. Garnett, jun. (*Review*), 587

Kelley Statistical Tables, The, Prof. T. L. Kelley (*Review*), 741

Kent Zoological and Botanical Gardens, [1839], 259

Kenya, Report on a Visit to, Dr. I. B. Pole-Evans, 255

Kenya's Pastoral Needs, 255

Kepler: Johannes, Gesammelte Werke, Band 1: Mysterium Cosmographicum. De Stella Nova, Herausgegeben von Max Caspar (*Review*), 223; Regiomontanus and, Prof. H. C. Plummer (*Review*), 223; Johannes, Gesammelte Werke. Band 2: Astronomiæ Pars Optica, Herausgegeben von F. Hammer (*Review*), 306
Kepler's: Approach to Optics, Prof. H. C. Plummer (*Review*), 306; Law of Refraction, Dr. R. A. Houstoun, 441
Keto-Acids in Green Plants, Estimation and Occurrence of, Prof. A. I. Virtanen, Dr. A. A Arhimo and Dr. H. Suomalainen, 597
Kidney Function, Role of the Renal Innervation in, Dr. N. S. Rustum Maluf, Dr. R. W. Clarke and Dr. K. W. Thompson, 292
Kiliwa Indians of Lower California, P. Meigs, 675
Kinetic Theory, Growth of the, Prof. R. H. Fowler (*Review*), 993
Klima, Wetter, Mensch, E. Brezina, W. Hellpach, R. Hesse, E. Martini, B. de Rudder, A. Schittenhelm, A. Seybold and Prof. L. Weickmann. Herausgegeben von H. Woltereck (*Review*), 1066
Knowledge, Useful, Society for the Diffusion of, [1839], 219
Kristallstrukturlehre, Angewandte, Dr. E. Brandenberger (*Review*), 587

Labour, Ministry of, Report for 1938, 107
Lamellibranchia, Reduction of the Ctenidia in the, R. D. Purchon, 206
Lancashire and Cheshire Fauna Committee, twenty-fifth annual report of the, 1042
Land: Drainage, Steam Applied to [1839], 301; -Speed Record, New, J. Cobb, 438; Utilization in Australia, Prof. S. M. Wadham and Prof. G. L. Wood (*Review*), 647
Lantana, Entomological Control of, 18
Latitude at Greenwich, Variation of, Tidal Effect on the, Dr. H. Spencer Jones, 162
Lavoisier, Priestley and, The Newer Views on, Sir Philip Hartog, 232
Lawn Craft, Practical, R. B. Dawson (*Review*), 581
Lawns, Research on, 627
Leadership: The Basis of, 343; The Price of, J. Middleton Murry (*Review*), 343; in Democracy, Lord Lloyd (Walker Trust lecture), 359
Leaf Cuttings, W. Ll. McCaskie, 161
League: The, from Year to Year (1938), 239; of Nations: Annual Report on Child Welfare, 281; Health Organization of the, 412; and the Rule of Law, 1918–1935, The, Sir Alfred Zimmern, Second edition (*Review*), 742
Least Squares, Some Notes on, Dr. W. E. Deming (*Review*), 585
Leather Chemists, Conference of, 603
Leeds University: election of Dr. M. G. Evans as professor of physical chemistry, and Dr. J. B. Speakman, professor of textile industries, 15; 47; Dr. R. G. S. Hudson as professor of geology, 16; 47; F. Whalley appointed lecturer in anæsthetics, H. Agar tutor in obstetrics and gynæcology, A. S. Johnstone lecturer in radiology, and R. V. Riley research assistant in fuel, 47; Report of the Department of Pathology and Bacteriology, for 1937 and 1938, Profs. M. Stewart and J. W. McLeod, 109; Dr. E. C. Stoner elected professor of theoretical physics, Dr. N. H. Chamberlain appointed lecturer in textile chemistry, A. Johnson assistant lecturer in weaving mechanism, Dr. C. S. Whewell assistant lecturer in finishing and research assistant in the textile department, J. W. Roderick and W. A. Linning lecturers in engineering, J. F. Gaunt research assistant in dyeing and Dr. J. Stubbs temporary research assistant (for bracken investigation), 219; Prof. F. A. Crew invited to deliver the Clive Behrens lectures in 1939–1941, 219; Diploma in Fuel and Refractory Materials, 242; Donation by the West Yorkshire Coal Owners' Association to the Mining Department, 762
van Leeuwenhoek: Alle de brieven (The Collected Letters of Antoni van Leeuwenhoek), Deel (part) 1, (*Review*), 956; The Complete Correspondence of, Prof. F. J. Cole (*Review*), 956
Legume Nodule Metabolism and Nitrogen Fixation, F. E. Allison, C. A. Ludwig, S. R. Hoover and F. W. Minor, 711
Leguminosæ, Nodule Organisms of the, J. K. Wilson, 335
Leguminous Symbiosis, Utilization of Carbohydrates in, Dr. G. Bond, 906
Leonardo da Vinci Exhibition at Milan, The, 337
Lepchas of Sikkim, The (*Review*), 96
Leptospiroses, Dr. Walch-Sorgdrager, 412
Lettuce, Ring Spot Disease of, Greta B. Stevenson, 120
Ley Farming, The Case for (*Review*), 263
Library Education, Professional, Nora E. Beust, 240
Light: from Extra-Galactic Nebulæ, Interpretation of the Red-Shifts of the, M. E. J. Gheury de Bray, 285; Chemical Powers of, [1839], 526; Coloured, Velocity of, J. S. Hall, 871; Velocity of, Measurements of the, Earl Kitchener, M. E. J. Gheury de Bray, 945; from Plants [1839], 1024
Light Elements, Beta-decay of, Connexion between the Life-time of the Meson and the, Dr. C. Møller, Prof. L. Rosenfeld and Dr. S. Rozental, 629;
Lighting, Ultra-Violet, R. H. Finch, 437

Matière et le Rayonnement, Le Principe de Correspondance et les Interactions entre la, Prof. L. de Broglie, 544
Matrices, Elementary, and some Applications to Dynamics and Differential Equations, Dr. R. A. Frazer, Dr. W. J. Duncan and A. R. Collar (*Review*), 650
Matter, Structure of, X-Ray Analysis and the, Sir William Bragg, 961
Maya: Mounds of British Honduras, late Dr. T. W. Gann, 252; Ancient, Cranial Deformation among the, A. J. E. Cave, 447
Measles in the Fertile Hen's Egg, Propagation of the Agent of, Dr. G. Rake and M. F. Shaffer, 672
Mechanical Force due to an Electron Stream, Dr. P. Selényi, 838
Mechanics: and Chemistry, Practical, Proposed Society for, [1839], 488; Applied: (*Review*), 728; Fifth International Congress for, Proceedings of the, edited by J. P. Den Hartog and H. Peters (*Review*), 728; The Teaching of, J. H. Awbery, 792
Medical: Scientific and, Research, Fellowships for, 168; Research Council, Prof. A. J. Clark and Prof. T. R. Elliott appointed members of the, 282; Schools in America, A Discourse upon the Institution of, Dr. John Morgan. With an introduction by A. Flexner (*Review*), 308; and Veterinary Science, Institute of, Adelaide: Opening of New Laboratories, Sir Charles Martin, 392; *Journal of Australia*, Silver Jubilee No., 508; Books, Rare, 704; Research Council, Prof. E. D. Adrian appointed a member of the, 905
Medicina aborigen americana, Dr. R. Pardal (*Review*), 308
Medicine: Early Medieval, with Special Reference to France and Chartres, Prof. L. C. MacKinney (*Review*), 308; History of, Dr. J. D. Rolleston (*Review*), 308; State-Craft and (*Review*), 345; Forensic, Recent Advances in, Dr. S. Smith and Dr. J. Glaister, Second edition (*Review*), 371; in Modern Society, D. Riesman (*Review*), 371; in Ancient Ireland, Dr. T. P. C. Kirkpatrick, 543
Medium High Velocities, A New Method of Determining *e/m* for, Dr. J. Aharoni, 203
Melandrium, Sex-determination in, H. E. Warmke and A. F. Blakeslee, 252
Mellon Institute: Dr. R. S. Tipson and Dr. W. Carlson appointed fellows in the department of research in pure chemistry of the, 507; Dr. G. O. Ebrey appointed Fleming fellow in the, 592
Mellor's Modern Inorganic Chemistry, revised and edited by Dr. G. D. Parkes in collaboration with Dr. G. W. Mellor (*Review*), 584
Mental: Disease and War, Prof. O. Kinberg, 409; Tests, Natural Variances of, and the Symmetry Criterion, Prof. G. H. Thomson, 516
Merseyside Naturalists' Association, appointments of the, 1042
"Merton Catalogue", The, Pamela F. Maude, 120
Mesolithic Settlement in Surrey, A, 525
Mesomerism and Orientation, Dr. G. Baddeley, 444
Meson: Classical Dynamics of the, Prof. D. Iwanenko, 77; and Cosmology, The, Dr. D. S. Kothari, 548; Connexion between the Life-time of the, and the Beta-Decay of Light Elements, Dr. C. Møller, Prof. L. Rosenfeld and Dr. S. Rozental, 629; Pairs, Evidence for Occurrence of, Dr. H. J. J. Braddick and G. S. Hensby, 1012

Mesotron: Instability of the, and the Gravitational Constant, Prof. P. M. S. Blackett, 30; Life-time of the, Prof. I. M. Freeman, 667
Mesotrons in the Upper Atmosphere, Intensity of, Dr. E. G. Dymond, 782
Metal Objects, Ancient, 675
Metallurgical Research, Modern, Development and present state of, Prof. F. Wever, 45
Metals: and their Alloys, Sir Harold Carpenter and Dr. J. M. Robertson, 2 Vols.; Prof. A. M. Portevin (*Review*), 612; Institute of, Election of Officers, 905
Metamorphism and Igneous Action, Prof. H. H. Read, 427; 729; 772
Metaplasia and Adenoma-like changes in the Uterus of Rats injected with Sex Hormones, Dr. V. Korenchevsky and K. Hall, 1048
Meteorites, Age of, Dr. F. A. Paneth, 639
Meteors, August, seen at Breslau [1839], 301
Methane under Pressure, Specific Heat of, O. N. Trapeznikowa and G. A. Miljutin, 632
Methyl: Radicals, Reactions of, H. S. Taylor and J. O. Smith, 336; Esters of Monocarboxylic Fatty Acids, Oxidation of, by Normal and Neoplastic Tissue, Dr. E. Ciaranfi, 751
Methylamine, Gaseous, Raman Spectrum of, Kirby-Smith and Bonner, 1018
Mexican: Loggerhead in Europe, The, D. Deraniyagala; H. W. Parker, 156; Mummies [1839], 169; Mosaic, R. Gallop (*Review*), 883
Mexico: An Eye-witness of, R. H. K. Marett (*Review*), 883; Present and Past (*Review*), 883; Magic in, Dr. R. Gessain, 1033
Miasmata and Contagia, On, J. Henle, Translated by Dr. G. Rosen (*Review*), 896
Mice, Hybridization and Tumour Formation in, C. C. Little, 1052
Microbes: by the Million, H. Nicol (*Review*), 998; More about, Prof. R. T. Hewlett (*Review*), 998
Microscopy: One Hundred Years of, the Royal Microscopical Society, Prof. R. T. Hewlett, 850
Migration and Environment, Prof. H. L. Shapiro, with the field assistance of F. S. Hulse (*Review*), 177
Military Service and the Professional Institutions, 749
Milk for Mothers and Children, 474
Milne-Shaw Seismograph, Attachment for a, J. H. Peters, 81
Mind, The Factors of the (*Review*), 532
Mineralogical Society, Election of Officers, 862
Mineral: Tables: for the determination of Minerals by their Physical Properties, Prof. A. S. Eakle. Third edition, revised by Prof. A. Pabst (*Review*), 742; Supplies, Strategic, G. A. Roush (*Review*), 921; Names (*Review*), 958
Minerals, New, Descriptive List of the, 1892–1938, G. L. English (*Review*), 958
Mines: Research Board, Safety in, Seventeenth Annual Report of the, 840; Department of, G. M. Harvey Appointed Electrical Inspector; J. A. B. Horsley to Undertake Special Duties relating to Electrical Supplies, etc., 862
Miocene Stratigraphy of California, R. M. Kleinpell (*Review*), 1030
Mist Particles, Evaporation of, and its bearing on Air Sterilization, S. R. Finn and E. O. Powell, 864
'Modern Man' in Eastern Asia, Prof. F. Weidenreich, 1097
Mohs, Friedrich (1773–1839), 564
Molecular Films, Built-up, Evaporation of, Dr. S. J. Gregg and Dr. E. E. Widdowson, 666
Mollusca of the John Murray Expedition, N. B. Eales; H. G. Stubbings, 484
Molluscs, Larval Trematodes in, Dr. Annie Porter, 715
Monoacetoneglucose, a new, The Ethyl-Thioglucosides and, Brigl, Gronemeier and Schultz, 680
Monolayers, Reactions with, and their Biological Analogues, Prof. E. K. Rideal and Dr. J. H. Schulman, 100
Monosilane, New-Iodine and Fluorine Derivatives of, A. G. Maddock, G. Reid and Dr. H. J. Emeléus, 328
Montserrat, the Volcano-Seismic Crisis at, 1933–1937, F. A. Perret, 677
Moral Rearmament, Science and, 303
Morphogenetic Forces, Order of Magnitude of, Dr. C. H. Waddington, 637
Motion Picture Sound Engineering (*Review*), 374
Mountain Building, A Theory of, D. Griggs, 602
Mud Bricks, Acoustic Properties of, F. H. Constable and M. K. Mahas, 33
Municipal Self-Government in Britain, G. M. Harris, 1060
Murdock, William (1754–1839), 842
Muscle: Experimental Verification for, A Mechanism for the Concentrating of Potassium by Cells, with, Prof. E. J. Conway and P. J. Boyle, 709; Electrolytes in, Localization of, Prof. E. J. Conway, Dr. F. Kane, P. J. Boyle and H. O'Reilly, 752; Anserine in, Possibility of Determination by Titration, Dr. E. C. Bate Smith, 1015
Museum: The, and the School, 89; as an Aid to the Encouragement of Arts, Manufactures and Commerce, Lord Amulree, 124
Museums: and Education, Earl De La Warr, 124; 626; and World Peace, Don Salvador de Madariaga, 124; Association: Jubilee Conference at Cheltenham, 124; of the Past and Needs of the Future, Viscount Bledisloe, 124; Natural History, Function of, Dr. W. E. Swinton, 125; of Ipswich, Report 1929–1938, 281; and Education, J. Wilkie, 626; and the War, 778
Music in Mental Diseases, Dr. A. H. Harrington, 1008
Mycenean: Athens discovery, Prof. T. L. Shear, 188; Greece, Further discoveries in, 360
Myers, F. W. H., The Life-work of My Friend, Sir Oliver Lodge (*Review*), 1027
Myosine and Adenosinetriphosphatase, Prof. W. A. Engelhardt and M. N. Ljubimowa, 668
Myristicin, Synthesis of, V. M. Trikojus and D. E. White, 1016
Myzus ornatus a Vector of Potato Viruses, J. B. Loughnane, 785

Names, Place and Personal, Changing Fashions in, L. F. Salzman, 85
Narcissus Mosaic, Studies on, F. A. Haasis, 448; Leaf Diseases, Indirect Damage by, P. H. Gregory, 984
Nasturtium, Garden, Genetics of the, Eileen Sutton, 838
National: Physical Laboratory: Annual Inspection and Visit of the Universities, 163; Trust, 1938–39, 359; Physical Laboratory Collected Researches. Vol. 24: Standards (*Review*), 458; Central Library, Twenty-third annual report of the, 507; Register, The, 609; Tuberculosis Association, Dr. G. B. Webb awarded the Trudeau medal of the, 628; Atlas of Great Britain, Proposed, 702; Service, Youth and, R. Brightman (*Review*), 723; Central Library, 974; University of Ireland, Conferment of an honorary doctorate on Prof. F. G. Donnan, 1044; Institute for Research in Dairying, Annual Report of the, 1087
Natural Resources, Conservation of, Prof. J. Stanley Gardiner (*Review*), 310
Nature: An Architect of, being the Autobiography of Luther Burbank. With biographical sketch by W. Hall (*Review*), 896
Naval Architects, Institution of, award of the Martell scholarship to N. W. Honey and the Earl of Durham prize to P. E. Bish, 546
Neanderthal Man in Italy, Discovery of, Dr. A. C. Blanc, 106
Nebular Red-Shift, Nature of the, Prof. E. Schrödinger, 593
Negro Education, Special Problems of, Prof. Wilkerson, 937
Nerve Fibre, Action Potentials Recorded from Inside a, A. L. Hodgkin and A. F. Huxley, 710
Nervous System, Physiology of the, Prof. J. F. Fulton (*Review*), 133
Neurohumour Production, Role of Dietary Choline in, Prof. D. Y. Solandt and Prof. C. H. Best, 376
Neuro-Physiology (*Review*), 133

Neutron : Dose in Biological Experiments, Measurement of, Dr. L. H. Gray and Dr. J. Read, 439 ; Emission, Delayed, accompanying Uranium Fission, Dr. K. J. Bostrøm, Dr. J. Koch and Dr. T. Lauritsen, 830

Neutrons : High-velocity, Energy of, by the photographic method, Dr. C. F. Powell and Dr. G. E. F. Fertel, 115 ; from Uranium, Possible delay of the emission of, D. F. Gibbs and Prof. G. P. Thomson, 202 ; and other Ionizing Radiations, Quantitative comparison of the Biological Effects of, Dr. L. H. Gray and Dr. J. Read, 509 ; D-D-, Scattering of, W. D. Allen and C. Hurst, 509 ; Fission of Thorium by, Dr. Y. Nishina, T. Yasaki, H. Ezoe, Prof. K. Kimura and M. Ikawa, 547 ; and Radio-elements and their Biological Applications, Dr. J. Lawrence, Dr. W. B. Lewis, Dr. J. Read and Dr. L. H. Gray, 657 ; Slow, Resonance Capture of, and Emission of Gamma-Rays, I. Nonaka, 831

Newcomen Society, Annual meeting of the, Col. C. E. Davies elected president, 861

New Lamps for Old, Dr. H. W. Melville, 604

Newton's : Correspondence, 65 ; Unpublished Letters, J. Pelseneer, 901

New : York Cancer Committee, award of the Clement Cleveland medal to Mlle. Eve Curie, 324 ; Zealand : Centenary Celebrations in, 859 ; Department of Scientific and Industrial Research, Thirteenth Annual Report, 873

Nicotiana, Trisomic, T. H. Goodspeed and P. Avery, 1095

Nicotinic Acid, Pentose-nucleotides and Anæmia, Dr. J. P. McGowan, 244

Night Sky in : July, 29 ; August, 199 ; September, 362 ; October, 591 ; November, 748 ; December, 938 ; January, 1087 ; Mechanism of Nitrogen Excitation in the, Prof. J. Cabannes and Rose Aynard, 442

Nile Basin, The, Vol. 5 : The Hydrology of the Lake Plateau and Bahr El Jebel, Dr. H. E. Hurst and late Dr. P. Phillips (*Review*), 495

Nitric Oxide in the Earth's Upper Atmosphere, Prof. J. Kaplan, 152

Nitrogen : Peroxide, Reaction between Hydrogen and Oxygen Sensitized by, Prof. R. G. W. Norrish and F. S. Dainton, 30 ; Fixation and Nutrition (*Review*), 134 ; Can Rusts Fix, Dr. B. d'Oliveira, 480 ; Fixation, Legume Nodule Metabolism and, F. E. Allison, C. A. Ludwig, S. R. Hoover and F. W. Minor, 711 ; Isotopes on Metal Surfaces, Exchange between, Taylor and Jungers, 1053

Nobel : Prizes for Physiology and Medicine, Award of, to Prof. C. Heymans and Prof. G. Domagk respectively, 777 ; Laureates, Award of the Chemistry Prize for 1938 to Prof. R. Kuhn, that for 1939 to Prof. A. Butenandt and Prof. L. Ruzicka, 858 ; the Physics Prize of 1939 to Prof. E. O. Lawrence and that for Literature to N. F. E. Sillanpää, 859

"Nomenclator Zoologicus", 279

Nomogram : The, The Theory and Practical Construction of Computation Charts, H. J. Allcock and J. R. Jones. Second edition (*Review*), 369

Non : -Adaptation, Reactions of Acclimatization and of, Prof. M. Piery and Prof. J. Enselme, 731 ; -Ferrous Metals Research Association, British, Dr. H. Moore, 83

North : American Indian Music, Miss Frances Densmore, 837 ; -East Coast Institution of Engineers and Shipbuilders, awards of the, made to Dr. T. W. F. Brown, A. Emerson, Dr. S. F. Dorey, J. Boele, W. T. Atkinson and J. Dawson, 665 ; of England Institute of Mining and Mechanical Engineers, F. P. Mills appointed honorary secretary of the, 150 ; Africa, Rock Art in, R. Vaufrey, 1052

Nose, Human, Ontogeny and Phylogeny of the, C. B. Benedict, 252

Nova Herculis, 1934, Nebular Spectrum of, The Forbidden $^{3}P_{2}$-$^{1}D_{2}$ Line of O III in the, Dr. J. Dufay and Dr. M. Bloch, 593

Novæ, Spectra of, Origin of the λ 4932 Emission in the, A. B. Wyse, 1090

Nuclear : Reactions in the Continuous Energy Region, Prof. N. Bohr, Prof. R. Peierls and Dr. G. Placzek, 200 ; Isomerism, Recent Experimental Results in, Dr. B. Pontecorvo, 212 ; Matter, Phase Transitions of, Dr. I. Gurevich, 326 ; Forces, Field Theory of, The Electric Quadrupole Moment of the Deuteron and the, Dr. C. Møller and Dr. L. Rosenfeld, 476 ; Reactions in Stellar Evolution, Prof. G. Gamow, 575 ; 620

Nucleoli, Satellites and Sex Chromosomes, Prof. R. R. Gates, 794

Nucleolus, Relation of the, to Secondary Constrictions, Miss A. M. Melland ; Prof. R. R. Gates, 980

Nudibranchiate Mollusca, Nomenclature of, Prof. W. Garstang, 481

Number Symbolism : Mediæval, Its Sources, Meaning and Influence on Thought and Expression, Prof. V. F. Hopper (*Review*), 586

Numbers, Theory of, An Introduction to the, Prof. G. M. Hardy and Prof. E. M. Wright ; Dr. H. Davenport (*Review*), 347

Nutrition : and the Public Health, 186 ; Elements in, W. Godden, 556 ; during War-time, Sir John Boyd Orr, 733

Oceanographical Results from Central America, 545

Œnothera, Position effect in, D. G. Catcheside, 837

Œstrogen Depot Formation, Dr. P. G. 'Espinasse, 1013

Œstrone, Isolation of, from the Adrenal Gland, D. Beall, 76

Oil : -Water Interfaces, Potentials at, R. B. Dean, 32 ; Fires in Power Stations, Preventing, 147 ; and its Uses, 1039 ; Lord Cadman appointed honorary adviser on, to the Secretary for Mines, 1088

Oils, Fats and Detergents, Progress in, P. W. Tainsh, 216

Old Age : Mental Hygiene in, Dr. G. Lawton, 902 ; Studies of (*Review*), 995

One Day Telleth Another, Stephen A. and Margaret L. Ionides (*Review*), 1028

Ontario Research Foundation, Report for 1938, 279

Opossum, Common Australian, Ambisexual Action of Progesterone as observed in the, A. Bolliger and A. Carrodus, 671

Optical Lever Method, Determination of Growth-Rates by the, Dr. W. A. Beck, 786

Orchids, Hybrid Wild, of Great Britain, P. M. Hall, 85

Ordnance Survey Plans, Brig. A. B. Clough, 590

Organizer Phenomena, Chemical aspects of, Dr. J. Needham, 561

Organs : in Vitro, The Culture of (*Review*), 95 ; The Culture of, A. Carrel and C. A. Lindberg (*Review*), 95

Oriental : Peach Moth in Australia, G. A. H. Helson, 913 ; and African Studies, School of, Annual Report, 1938–39, 1006

Ornithology, British Trust for, Fifth annual report of the, 108

Osmunda regalis, Spiral Structure in, I. Manton, 716

Ospedale del Perdono, Milan, Prof. G. Sollazzo nominated director of the, 905

Outlaw of the Air, Leslie Brown (*Review*), 1079

Oxaloacetic Acid in the Leguminous Plants, Prof. A. I. Virtanen and A. A. Arhimo, 36

Oxford University : School of Forestry, 67 ; Dr. L. A. Woodward appointed fellow of Jesus College and tutor in chemistry, 301 ; T. K. Penniman appointed curator of the Pitt-Rivers Museum, 701 ; R. S. G. Rutherford appointed a research officer in the Institute for Research in Agricultural Economics, 875 ; H. G. Champion appointed professor of forestry ; Miss A. Pellew awarded the Edgell Sheppee scholarship in engineering science, 990

Oxide Films on Light Metals, Electron Diffraction Examination of, Ichirô Iitaka and Shigeto Yamaguchi, 1090

Oxygen : Hydrogen and, Sensitized by Nitrogen Peroxide, Reaction between, Prof. R. G. W. Norrish and F. S. Dainton, 30 ; Apparatus, Open type, P. J. H. Unna, 114

Oysters (*Ostrea edulis*), Breeding of, in Tanks, H. A. Cole, 642

Pacific : South, Currents in the, 148 ; Science Congress, Sixth, 640 ; Entomological Survey, 826 ; Tides, Between, E. F. Ricketts and J. Calvin (*Review*), 1078
Pain, The Problem of, Prof. P. T. Herring, 770
Paiute Bands, Northern, O. C. Stewart, 601
Palaeobotanical Retrospect, A, 395
Palaemonetes varians (Leach), Osmotic Behaviour of, N. Kesava Panikkar, 866
Paleobotany, Textbook of, W. C. Darrah (*Review*), 226
Palestine, Population Statistics, 1010
Palladium-Deuterium Equilibrium, L. J. Gillespie and W. R. Downs, 757
Panama Canal as a Fish Highway, S. F. Hildebrand, 756
Papain essential to its Activity, Nature of a Group in, Prof. A. K. Balls and H. Lineweaver, 513
Paracelsus, Forthcoming celebration of the quatercentenary of the death of, 29
Paramecium, An Increase in the Rate of Growth of, subjected to the Blastogenic Hydrocarbon 3 : 4-Benzpyrene, J. C. Mottram, 154
Paris : Academy of Sciences : election of Prof. W. L. Bragg as a *correspondant*, 150 ; Prof. S. Timoshenko elected a *correspondant*, 199 ; Pasteur Institute, award of the gold Pasteur medal to Dr. H. Plotz and Prof. A. Saenz, 474
Parliamentary and Scientific Committee of the House of Commons, L. F. Plugge elected chairman of the, 1009
Parthenogenesis, Artificial, and Chromosome Constitution, T. Kawamura, 209 ; Experimental, Recent Work on, Prof. A. D. Peacock, 1036
Patent Medicines, Marking of, 186
Patents : in War Time, 580 ; Designs and Trade Marks, Fifty-sixth Report of the Comptroller-General, 1938, 641
Pathological Processes, Adaptation in, Dr. W. H. Welch. With an Introduction by Dr. S. Flexner (*Review*), 308
Pawnee Archaeology, W. R. Wedel, 983
Peace : Seeking and Securing the, 607 ; Aims, 701
Pea Leaves, An Inhibitor of Growth extracted from, Dr. R. Snow, 906
Peintures, conservation et de la restauration des, Manuel de la (*Review*), 586
Peking, National University of, Monlin Chiang, 242
Pelargoniums, Sir Arthur W. Hill, 639
Penaeids of the John Murray Expedition, Dr. Ramadan, 518
Pepsin Preparations, Crude, Existence of several Active Components in, V. Desreux and R. M. Herriott, 287
Periodic Action, An easily arranged, E. E. and Dr. I. W. Wark, 833
Personality in Formation and Action, Dr. W. Healy (Thomas W. Salmon memorial lectures), (*Review*), 588
Peru : Institute of Cotton Technology of the National Agricultural Society of, Dr. S. C. Harland appointed director of the, 705 ; Archaeology in, Recent Progress, H. J. Braunholtz, 841
Petrol, Substitutes for, 622
Pétrole ; Les Gisements de, Géologie, Statistique, Economie, Prof. G. Macovei (*Review*), 1080
Petroleum Production Engineering : Oil Field Exploitation, Prof. L. C. Uren. Second edition (*Review*), 1080
Petroleum, No. 1, 905
Pharmaceutical Society of Great Britain, award of the Hanbury medal to T. E. Wallis, 144
Pharmacognosy, A Textbook of, T. C. Denston. Third edition (*Review*), 192
Pharmacopoeia, The Extra, Martindale. Twenty-first edition. In 2 vols. Vol. 2 (*Review*), 195
Philippine Pagans : the Autobiographies of Three Ifugaos, R. F. Barton (*Review*), 1077
Philosophies, Natural and Political, Sir Richard Gregory, Bt. (*Review*), 764
Phoronis hippocrepia Wright, A new record of, E. W. Knight Jones, 836
Phosphatide Exchange between Plasma and Organs, Dr. L. Hahn and Prof. G. Hevesy, 204
Phosphatides of the Plasma and the Corpuscles, Interaction between the, Dr. L. Hahn and Prof. G. Hevesy, 72
Phosphorus Halides, Fluorination of, H. S. Booth, S. G. Frary and F. B. Dutton, 1017
Photography : to Astronomy, Application of, [1839], 87 ; in Scientific Research, 356
Physical : Laboratory, Apparatus for the, 190 ; Fitness, Assessment of, Prof. D. Burns, 431 ; 466 ; Development in School Boys, Standards of, H. B. Norman, 518 ; Size and Proportions, Factors Determining, J. I. Cohen, 944
Physico-Chemical Experiments, Prof. R. Livingston (*Review*), 897
Physics : On Understanding, Prof. W. H. Watson (*Review*), 196 ; Demonstration Experiments in, edited by Prof. R. M. Sutton (*Review*), 197 ; for Technical Students : Sound, Electricity and Magnetism, Light, Prof. W. B. Anderson. Third edition (*Review*), 373 ; To-day, J. A. Clark, F. R. Gorton and F. W. Sears (*Review*), 588 ; Practical : Higher School Certificate, E. Armitage (*Review*), 743 ; W. F. F. Shearcroft and J. H. Avery (*Review*), 743 ; Elementary Survey of, a Non-mathematical Presentation with a special supplement for Pre-medical Students, Prof. A. E. Haas and Prof. I. M. Freeman (*Review*), 744 ; The Psychology of, B. Stevens (*Review*), 1081
Physik, chemischen, Lehrbuch der, Prof. A. Eucken. Zweite Auflage. Band 1 (*Review*), 193
Physiological Genetics, An Experimental Attack on some Problems of, Dr. W. Braun, 114
Physiology, Human, A Text in, Prof. C. H. Best and Prof. N. B. Taylor (*Review*), 228
Phytohormones, Études et recherches sur les (*Review*), 192
Phytoferol : a Standardized Solution of Vitamin E, 1008
Pig : Chromosomes of the, Prof. F. A. E. Crew and P. C. Koller, 385 ; Growth of the Mandible in the, Prof. H. A. Harris, 552
Pilgrim Trust Lecture, Second, Sir William Bragg, 15 ; 21
Pitch-Crust Fungus, Parasitism of the, W. H. Wilkins, 253
Pithecanthropus and Sinanthropus, The Relationship between, Dr. G. H. R. von Koenigswald and Prof. F. Weidenreich, 926 ; 933
Plague and other Tropical Diseases, The Story of, Dr. Clayton Lane (*Review*), 801
Planetary Co-ordinates for the years 1940–60 referred to the Equinox of 1950·0 (*Review*), 899
Planets : and Sunspots (*Review*), 726 ; Minor, of the Hecuba Group, Prof. A. O. Leuschner (Halley lecture), 871
Plankton Culture, Large-scale, Dr. H. Pettersson, Dr. F. Gross and F. Koczy, 332
Plant : Taxonomists, Geographers and Ecologists, Address Book of, Forthcoming publication of an, 150 ; Phylogeny, Dr. H. Hamshaw Thomas (*Review*), 226 ; Living : Botany of the, Prof. F. O. Bower. Third edition. With the assistance of Prof. J. M. F. Drummond and Dr. G. Bond (*Review*), 400 ; Dr. C. R. Metcalfe (*Review*), 400 ; Structure, Interpretation of, Prof. D. Thoday, 432 ; 571 ; Physiology : Experiments in, a Laboratory Text-Book, Dr. W. E. Loomis and Dr. C. A. Shull (*Review*), 583 ; Geography, Principles of, Dr. W. B. Turrill, 715 ; Hormones and their Practical Importance in Horticulture, Dr. H. L. Pearse, 747 ; Breeding in the light of Genetics, Dr. K. Mather, 820 ; Growth-Substances, Experiments with, for the Rooting of Cuttings, Dr. C. R. Metcalfe and W. G. Templeman, 1043
Plantes des Montagnes, Ce qu'il faut savoir des, P. Du Manoir (*Review*), 893
Plants, Fecundation and Development of, [1839], 875
Pleistocene Bird's Egg, A, A. Wetmore, 790
Plough-up Policy, The, and Ley Farming, Sir George Stapledon (*Review*), 263
Plums, Stored, Breakdown in, W. H. Smith, 1006

Poisson de rivière, La mécanique du, G. Denil (*Review*), 567
Poland: Electrical Progress in, 341; The Fourth Partition of, 579; Abroad, Institution of a University of, 1044
Polarograph, The, 904
Political and Economic Planning, 144
Polychaete Worms, Intermittent Activity in, Dr. G. P. Wells, 940
Polymolecular Films, Absorption of, in the Infra-Red, Dr. G. B. B. M. Sutherland and W. T. Tutte, 707
Polyploids are more Variable than their Original Diploids, Prof. D. Kostoff, 868
Polyploidy induced by Colchicine and its Economic Possibilities, Dr. G. H. Bates, 315
Population: Decline of, Viscount Samuel, Lord Dawson of Penn, Lord Stamp, and others, 17; Growth, Factors in (*Review*), 55; the Natural History of, Prof. R. Pearl (*Review*), 55; of the World in 1937, 150; Problems of Housing Estates, N. Williams, 166; To-day's Question, G. F. McCleary (*Review*), 193; Improvement, Social Biology and, Prof. F. A. E. Crew and others, 521; The Pressure of, 991
Positivisme, origines intuitives du, Essai sur les, Dr. P. Ducassé (*Review*), 587
Potassium: Liberation of, by Acetylcholine in the Central Nervous System, Dr. W. Dulière and O. Loewi, 244; Dihydrogen Phosphate, Isotope effect in, Dr. A. R. Ubbelohde and I. Woodward, 632; A Mechanism for the Concentrating of, by Cells, with Experimental Verification for Muscle, Prof. E. J. Conway and P. J. Boyle, 709; Carbohydrate and, Metabolism in Normal and Adrenalectomised Animals, Connexion Between, Prof. F. Verzár and J. C. Somogyi, 1014; *Molybdocyanide Dihydrate, Structure of*, J. L. Hoard and H. H. Nordsieck, 1018
Potato Viruses, ***Myzus ornatus*** a Vector of, J. B. Loughnane, 785; Viruses in Garden and Field, Potential Hosts of, Dr. R. N. Salaman and W. R. S. Wortley, 1049; Root Eelworm, Control of the, J. Carroll, 1095
Poultry Advisory Committee of the Ministry of Agriculture and Fisheries, appointment to the, of Capt. G. Clifford and Prof. T. J. Dalling, 1010
Poznan University, Staff and Students of, held as hostages, 1044
Prague, University of, Germanization and the, 892
Pregnancy, Ancient Tests for, Dr. H. P. Bayon, 826
Préhistoire générale: Manuel de, Europe, Asie, Afrique, Amérique, Prof. R. Furon (*Review*), 737
Prehistoric: Society of Switzerland, Prof. V. Gordon Childe elected an honorary member of the, 65; *Indian Village, New Mexico, Dr. P. S. Martin*, 542; Rock Pictures in Dutch New Guinea, J. Röder, 946
President, The Steamship, [1839], 643
Priestley and Lavoisier, The newer views on, Sir Philip Hartog, 232
Primitive Man, The Mind of, Dr. F. Boas. Revised edition (*Review*), 738
Procter International Research Laboratory, Prof. D. McCandlish appointed honorary director and W. R. Atkin honorary research assistant of the, 938
Progesterone, Ambisexual Action of, as observed in the common Australian Opossum, A. Bolliger and A. Carrodus, 671
Prolactin, response of the Pigeon Crop-Gland to, Sex Difference in the, Dr. S. J. Folley, 834
de Prony, Baron, 1755–1839, 219
Protein: Fractions in Solutions particularly Poor in *Proteins*, Precipitation of, Dr. P. Ladewig, 76; Molecules, Apparent Shape of, H. Neurath, 386; Analysis of, by means of Deuterium-containing Amino-Acids, Dr. H. H. Ussing, 977
Proteins: Structure of, L. Pauling and C. Niemann, 336; A New Technique for the Spreading of, and the 'Spreading Number', Dr. D. Dervichian, 629; Amino Acids and, The Chemistry of the, edited by Prof. C. L. A. Schmidt (*Review*), 923
Protobranchiate Mollusca, Prof. C. M. Yonge, 601
Protons, Scattering of, by Protons, R. G. Herb, D. W. Kerst, D. B. Parkinson and G. J. Plain; and others, 254
Protoplasm: The Cell and, Symposium at Stanfor University, Prof. C. V. Taylor, 884
Proverbes et dictons Syro-Libanais; texte arabe, transcription, traduction, commentaire et index analytique, Prof. M. Feghali (*Review*), 582
Proverbs: Racial, A Selection of the World's Proverb arranged Linguistically, Dr. S. G. Champion (*Review*) 582
Prussian Academy of Sciences, election to the Physico-Mathematical Class, of Prof. A. Butenandt, Prof. K Meyer, Prof. A. Ludin, Dr. F. Seewald and Prof. J Bartels, 70
Pseudomonas aeruginosa, A Light-sensitive Strain of Miss Jane Meiklejohn, 908
Psychiatry in the Punjab, Lt.-Col. O. J. L. Patch, 662

SCIENCE, INDUSTRY AND SOCIETY

THE meeting of the Division for the Social and International Relations of Science of the British Association which was held last week in Manchester provided a particularly apt illustration of the twofold functions of the new Division. The formation of the Division is the outcome of the new recognition on the part of scientific men themselves of their responsibility for the social consequences of their discoveries, to which Dr. J. S. B. Stopford, the vice-chancellor of the University of Manchester, referred in his address of welcome. While, however, the formation of the new Division has been widely welcomed outside the ranks of scientific workers themselves, as indicated, for example, in the remarks of Mr. C. Woodcock, head of the economic and research department of the Trades Union Congress in the discussion, the meeting made it clear that educational work in this field must for some time to come be an important activity of the Division.

For this situation there are several reasons. In the first place, as Sir Richard Gregory pointed out in his introductory address as chairman of the Division, the prelude to effective action is clear thinking about the social implications of scientific work, of the uses that are being and could be made of science, of the abuse of scientific knowledge, and of the fuller use which could be made of it for promoting general social welfare.

Such educational activity is also of importance in securing the widespread support which is equally essential if scientific investigation is to be carried out in this field on any adequate scale. At the present time, as Sir Richard Gregory pointed out, the resources available for research on the effects on the community of scientific knowledge acquired or used are very meagre. Large funds already exist for industrial research, though the net annual expenditure of £600,000 of the Department of Scientific and Industrial Research—the most potent agent in Great Britain in promoting the application of science and scientific knowledge to industry—compares unfavourably with the national effort in other contries and might be trebled with advantage. No fellowships exist for inquiry into the effect of scientific and industrial change in the community, and a strong case could be made out for the organization and supply on a similar scale of facilities for research into the changes in the character and conditions of labour, the distribution of industries and population and the many other social problems involved in practical applications of scientific discovery.

It would indeed be difficult to choose two examples better calculated to illustrate the importance of the application of scientific method and research than the two industries—the cotton industry and the plastics industry—selected as the subject of the Manchester meeting. As

Dr. F. C. Toy pointed out, in the old-established cotton industry a period of great mechanical and chemical advance, up to the middle of the nineteenth century, in which the demands of the industry stimulated both scientific and mechanical discovery, was succeeded by one of comparative neglect and stagnation in spite of rapidly expanding trade. The scientific drive passed to the dyers or chemical industries, and scientific revival in the cotton industry only came about twenty-five years ago. Until 1910, there was scarcely a physicist in the industry, and this neglect of science by the industry well explains both the difficulties which from time to time the British Cotton Industry Research Association has experienced in securing support and the failure of the industry to utilize the results of scientific knowledge available for it.

Unquestionably this neglect of science has been a factor in the difficulties which the industry has experienced in meeting the competition of the new synthetic fibres. The development of fabrics which resist creasing or shrinking as well as stains, or which repel water, is largely due to fuller knowledge of molecular structure, and the development of crease-resistant cotton fabrics as a result of sixteen years research described by Sir Kenneth Lee is an example of the way in which scientific research can enable an industry to adapt itself to meet the demands of new conditions.

The value of a central research organization, however, as Dr. Toy pointed out, does not lie in the supply of new knowledge alone. It lies equally in the stimulus which it supplies to scientific and technical thought in the industry as a whole, while it should not be forgotten that industrial research often makes as important contributions to the advance of science itself as science does to that of industry. Indeed, this has been notably true in the development of the plastics industry, where scientific and technical advance have frequently been hand in hand. A remarkable example of this may be seen in the development of the new fibre 'Nylon' to replace natural silk

If the feature of the plastics industry is its direct dependence on scientific research, few industries illustrate more conspicuously the reaction of applied science on the community. Frequently the development of plastics has been linked up with the advance of other industries, but apart from this, plastics are not merely meeting new needs by making possible the cinema, the roll-film, the gramophone record and the electrical industry as we know it, but they are also displacing other materials for constructional purposes, and as Dr. V. E. Varsley and Mr. E. C. Couzens pointed out, offer a new media for the expression of handicraft, possessing possibilities not found in wood and metal. Moreover, we are only on the threshold of the real plastics age, in which materials will be built up by chemical synthesis to meet the great majority of specific requirements.

The technical significance of such developments and the possibilities and advantages inherent in them should not be allowed to blind us to the profound influence which they may have on social life as well as on individual industries. More and more, however, it is realized that industrial efficiency can no longer be computed in mechanical terms; it must take full account of the human factor, and it must also be considered in relation to the welfare or efficiency of society as a whole. We need, as Prof. H. Levy urged in his Pedler Memorial Lecture (which also formed a part of the Manchester meeting), a system of social accountancy, which would provide the information necessary for informed judgment on social proposals.

In directing attention to this need for a survey of the efficiency of our social machinery and the changes it creates in the community, Prof. Levy touched on the second function of the new Division. It is not concerned solely with the education of scientific and public opinion in the social consequences of scientific discovery, at least to the point of lucid thought about definite and specific problems and the provision of means for the investigation. It is equally concerned with the elaboration of the technique for the investigation of social change.

In his lecture, Prof. Levy made a number of suggestions in regard to the measurement of social change which deserve the attention of the Division. A study of the social relations of science implies an examination of the way in which scientific and technical applications are reflected in physiological and cultural development in the community. We require accordingly a complete survey of the appropriate indexes in all these fields. We require measures of the technical level in commodity production contrasted with what might conceivably be attained at any moment; the relative degree of research activity in various branches of science; indexes for physical fitness for various social classes and their resistance to certain diseases; housing standards and educational facilities compared with what might be attained with planning. Such indexes need not be more difficult to provide than the cost of living index.

The Manchester meeting of the new Division succeeded at least in providing impressive illustrations of the opportunities for the application of scientific method in the solution of problems of social change due to industrial development, no less than in industry itself. It may indeed be hoped that the meeting will encourage many more scientific workers to seek to bring to the solution of such problems the same attitude of mind and principles which they use in their research, and stimulate both the formulation of specific projects for investigation and the elaboration of the requisite technique and principles of investigation.

SCIENCE IN A CHANGING WORLD

Modern Science

A Study of Physical Science in the World To-day. By Prof. Hyman Levy. Pp. x+736. (London: Hamish Hamilton, Ltd., 1939.) 21s. net.

THE twentieth century has been an era of violence and change. In our acute awareness of this, we may fail to notice that in the midst of danger, insecurity and the destruction of human values and lives, a new order is insensibly being formed. Scientific men and practical men, starting from widely different viewpoints, are coming to think of things in the same way—one very different from that which satisfied us not so many years ago. Because of this very diversity of origin, it is difficult to grasp consciously what is happening, and yet that conscious grasp is what we feel we need most. Intellectual insecurity is only the counterpart of the present political insecurity of the world. That security can only be won by wide views and hard thinking. Prof. Levy's book is a notable contribution to the series of attempts to reformulate our knowledge in relation to the great internal and external changes it has undergone in the last few years. He has already written much upon this subject, but there is no doubt that "Modern Science" represents much more matured thought than any of his previous writings. Both those who are acquainted with Marxist views in science and those who are not will find it well worth their while to read carefully through its seven hundred pages.

The purpose of "Modern Science" is to bring into the scope of our thinking certain general considerations that have so far been relatively foreign to the tradition of scientific thought, and to show how these considerations are necessitated both by the internal developments of science and the discovery of new relations and contradictions in it, and by the increasingly acute impact of social events on the carrying out of scientific work. The book is addressed not only, and indeed not principally, to men of science, but also to intelligent persons in general. Because the language of science is not the common language, much explanation both of elementary and advanced scientific ideas is necessary, but the book is not so much an exposition of science as a criticism of the limitations of scientific thought and an indication of the lines along which it can be generalized and extended.

The four principal ideas which the author introduces with a wealth of examples are: the general interrelation of the processes of the universe and the consequent artificiality of scientific study in isolation; the prevalence of opposites both in the world of Nature and in our mathematical and physical ways of understanding it; the existence of critical changes of quality brought about by continuous quantitative processes; and the close and permanent interaction between the practical basis of social life and its intellectual interpretation in science. These are all ideas which until recently would have appeared strange and ridiculous to many scientific workers, and still seem so to many. The value of Prof. Levy's analysis is that he shows us that recent developments have made most of them an integral part of scientific thought. The quantum theory in particular brings out very clearly the significance of characteristic values of a physical variable and the presence of instability and discontinuous change. The theory of relativity, on the other hand, while appearing in one aspect as a culmination of the abstract and mechanical world view of Newton, is also one of the first recognitions of the need for comprehensiveness in the formulation of scientific law. From the new viewpoint, much of the science of the past is seen to be an answering of detail-problems, artificially isolated both in their antecedents and from the world around them. The new view does not alter science, but it does help to extend it, and in doing so to make it intrinsically more intelligible.

"Modern Science" is divided into seven parts. The first introduces science as a developing means of using and controlling energy. It shows how from the technical point of view we can have energy in abundance, but that we are still unable for political and economic reasons to make full social use of it. The final chapter, on the inversion of science, is particularly interesting. The second part contains an outline of the main arguments of the book in a most general and practical way. The third part, on the universe of symbols, takes us into mathematics and exhibits the history of mathematics as a continuous struggle to achieve comprehensiveness and freedom. The fourth contains a most penetrating study of Newton's laws and of their generalization in the eighteenth and nineteenth centuries, illustrated by a chapter on aerodynamics, which brings out the relations between theory and experiment. The inadequacy of the Newtonian view is led up to by a fifth part dealing with projective and non-Euclidean geometry. This leads to the sixth and most interesting section of the book, which discusses the actual content of the universe from cosmology to atomic structure, and incidentally the relativity and quantum theories. The seventh part gives a concrete example of applied physical science—its use in the development of illumination.

Finally, we have an epilogue which sums up in nineteen theses the difference between the older views of science and those associated with dialectical materialism. It is impossible to quote more than a few of them, but the following may stand as typical.

DIALECTICAL METHOD	MECHANISTIC METHOD
1. The history of science and the growth of its ideas are intimately bound up with the history of social needs. Whether science will advance rapidly, or be retarded, will depend on how far society is consciously organized to this end.	1. Science is a thing in itself and its use by society is purely extraneous. Science has its own history, that of the erection of a system of logically connected ideas.
2. Scientific truth emerges through the interplay of theory and practice. Truths are not only discovered but made and transformed into greater truths. They are changed in the process of discovery and of verification.	2. Truth is discovered. It lies in the background as an absolute.
4. In science man learns to think logically by the force of experimental practice. His logical perceptions have therefore a history of growth and they reflect the natural processes to which he has been mentally compelled to adapt himself.	4. Man thinks logically in an absolute way. Such processes are unchanging and they analyse events in the universe, forcing them into a previously determined logical pattern.
8. The laws of Nature describe statistical regularities and are changing.	8. The laws of Nature are absolute and unchanging.
11. Process change implies continual qualitative change by the resolution of internal 'contradictions' into a more embracing synthesis. This implies a changing cause-effect relationship in which in each pair elements and groups play a dual role with respect to each other.	11. Cause and effect follow each other in isolation and the laws of Nature are always of the simple cause-effect type.
18. Since science is a form of action in social life and since decisions regarding social action have to be made, there must be a specific type of scientific approach at each level of human activity, from controlled laboratory science to the making of social history.	18. Without complete knowledge no scientific decision can be arrived at. Complete knowledge is defined as that demanded by physical science. Social activity cannot be carried through, therefore, in a scientific manner.

The theses bring out very clearly how much better the ideas of relativity and the quantum theory fit in with the dialectical mode than they do with the mechanical. But as Prof. Levy points out later, the importance of the dialectical method lies even more in the relations of science to society than in science itself:

> "The scientific repercussions of a lack of the fullest appreciation of dialectical change in scientific work itself are slight. On the other hand, the social repercussions of a lack of appreciation of the dialectical changes produced by and on science in its interaction with society may be almost catastrophic. That this lack of appreciation exists is evident from the contradiction that persists in the minds of scientific men, and indeed all others who give thought to the matter, when they contrast the potentialities of science for abundance in social life with its adaptation as a means of ensuring scarcity." (pp. 708–709.)

This is a book for all scientific workers to read. It will provoke thought and discussion. Its length, which the need for elementary presentation makes necessary, is compensated for by the forcefulness and clarity of Prof. Levy's style, and by the excellence of the many illustrations.

J. D. BERNAL.

INSTINCTS OF THE HERD

The Social Life of Animals
By Prof. W. C. Allee. Pp. xiv+265+5 plates. (London and Toronto: William Heinemann, Ltd., n.d.) 12*s.* 6*d.* net.

WHEN Huxley wrote that among animals and among primitive men "Life was a continual free fight, and beyond the limited and temporary relations of the family, the Hobbesian war of each against all was the normal state of existence," he was, not for the first time, overstating the case. The idea that co-operation is as 'natural' and as fundamental as competition is at least as old as Empedocles. Darwin used the term 'struggle for existence' "in a large and metaphorical sense, including dependence of one being on another", and Herbert Spencer insisted that "from the dawn of life altruism has been no less essential than egoism". Patrick Geddes and Arthur Thomson used to impress upon their students the importance of sociality as a factor in animal evolution, and Kropotkin, uncritical though he was, did good service by pointing out the inadequacy of the gladiatorial theory of life. In recent years, the very active school of animal ecology directed by Prof. Allee in Chicago has given much attention to the problems of animal aggregations, seeking to discover the links that hold them together and the advantages, individual or racial, derived from them. In this volume, based on a course of lectures delivered at the Northwestern University, he gives a summary of the more important results of these researches and discusses their significance.

After a brief historical introduction, which might have been expanded with advantage, the author mentions those aggregations of individuals in which the connexion is structural, as in the groupings of fissiparous Protozoa that, presumably, gave rise to the Metazoa, and in the colonial Cœlenterates and the like. He then goes on to describe instances of swarms that are merely swept together by environmental action as plankton animals are by ocean currents, or that are attracted together to some favourable niche of the environment as Protozoa cluster round an air-bubble on the microscope slide or bats assemble in a suitable cave. We cannot tell when or where such accidental assemblages merge into those in which the individuals actively seek the company of their kind, or how mutual toleration leads towards co-operation and mutual aid.

The advantages—or, more precisely, the 'survival-value'—of these aggregations are sometimes obvious; mass defence against predators is visibly effective; but often they are more recondite. There seems to be a 'confusion effect', as when small birds flock together in presence of a hawk; the enemy's attention is distracted, and he is less likely to be successful than when he can concentrate his attention on a solitary victim. It may perhaps not be true that "the wolf cares not how many the sheep may be" and it is certain that a goldfish will eat more water-fleas if it is given a few at a time than if it is presented with the whole bewildering mass at once. Sometimes the advantage is plainly physical, as when hibernating small mammals huddle together for warmth; sometimes it is more subtly chemical, as when it is demonstrated that goldfish thrive better in pond water that has been conditioned by the previous presence of other goldfish. The ill-effects of overcrowding are often lamentably plain, with animals as with men, but there is a growing body of evidence bearing on the less obvious evils of undercrowding in the most diverse organisms ranging from Protozoa up to elephants.

As we proceed up the scale of animal life these various assemblages tend to become organized into more or less definite societies. Even the hen-run has its 'peck-order', although the cock of the walk enjoys only a precarious sovereignty and a very little may turn him into the persecuted butt of his companions. Innumerable gradations lead up to the highly integrated communities of bees, ants and termites in which the various castes are structurally as well as functionally differentiated.

On all these, and many related subjects, Prof. Allee has much to say that is interesting and important, and much that will, we believe, be novel to zoologists who have not given special attention to this department of their science. He writes in a readable style and his explanations are generally, though not invariably, easy to follow. There are, however, one or two points that seem open to criticism.

Prof. Allee is an experimentalist rather than a field naturalist, and he appears somewhat to neglect or to undervalue the great mass of field observations that bear on his subject. It is perfectly true that, as he says, many of these observations "can only be recorded as more or less interesting anecdotes", but there are others, of which the details have been fully collected and scientifically analysed, that are at least as deserving of attention as the results obtained in the laboratory. It is noteworthy that, of the field observations thought worthy of discussion, some, like those relating to the elephant herds of the Knysna Forest and the Addo Bush (p. 89), are presented without the particulars necessary for forming a judgment on their significance.

The great advantage of the experimental method lies in the possibility of obtaining precise quantitative results. It demands a correspondingly careful handling of the numerical data in the exposition of these results. It is disappointing to find, therefore, that the very first table in the book (p. 38) flatly contradicts the interpretation of it given in the text. A reference to the original paper from which it is quoted shows that a transposition of figures has occurred. The diagrams on pp. 44 and 46 are taken from a paper still unpublished and they cannot, therefore, be checked, but the figures they contain give percentages widely different from those that are said in the text to be extracted from them. On p. 74 a certain coefficient is said to be "obtained by multiplying the number of fish by their average length in millimetres. . . ." A non-mathematical zoologist would get the same result by taking the sum of their lengths. In a book written in the United States and printed in England one may suspect difficulties in the matter of proof revision; but meantime Prof. Allee cannot complain if readers must suspend judgment on some of his conclusions.

One of the most telling chapters in the book is that entitled "Some Human Implications". There has been no more deplorable example of the crude application of biological principles to the complexity of human affairs than the attempt to justify international war in terms of the struggle for existence. Prof. Allee exposes very effectively the futility of this argument. If, on the other hand, co-operation, at first physiological, then instinctive, and latest of all, conscious, has been a factor in animal evolution no less important than competition, then biology does offer some hope to those who look forward to a better world order. In the meantime, alas, we, on this side of the Atlantic, must get on with our A.R.P.

W. T. CALMAN.

CRYSTAL CHEMISTRY

(1) An Introduction to Crystal Chemistry
By Dr. R. C. Evans. Pp. xi+388. (Cambridge: At the University Press, 1939.) 18s. net.

(2) Crystal Chemistry
By Dr. Charles W. Stillwell. (International Chemical Series). Pp. x+431+1 plate. (New York and London: McGraw-Hill Book Co. Inc., 1938.) 25s.

THE appearance of these two books is symptomatic of a new development in natural science, the birth of a comprehensive theory of the solid state. Both are the work of writers at least partly concerned with teaching, but whereas the first bears the firm impress of the university, the second is slightly technological, and reviews several interesting applications.

(1) Dr. Evans has assuredly written a volume which should never be far away from the mind and elbow of the serious student of the subject. A beginning is made by discussing in detail the forces which bind together the 'bricks' of which the crystal edifice is composed, after which the structures resulting from their interplay are examined systematically. Naturally, this latter portion of the book is much the larger of the two, since no important configuration is omitted. In addition, a place is found for a brief survey of liquid crystals, and for liquids themselves, and glasses. The author remarks that his intention has been to avoid overloading his pages with mere detail of crystal types: the effect is to maintain the reader's interest unabated.

The essence of Dr. Evans's thesis appears to the reviewer to be contained in the concluding discussion of Part 1; and indeed it could not have been better said. It is that the molecule, while all very well in the gaseous state, is not necessarily by any means such a helpful concept in crystals; in fact, it has been responsible for much over-emphasis upon the part played by the classical laws of chemistry. A somewhat similar restriction applies to valency, especially in intermetallic systems.

(2) To the student occupied in an orthodox course of chemical training, Dr. Stillwell's book will come as a welcome shaft of light. It has always been exceedingly difficult to introduce the properties (and indeed the very existence) of solids into such a curriculum without much artificiality. Crystal chemistry, treated as this volume treats it, will do much to help.

Perhaps of necessity the balance appears a little uneven: certain aspects like the silicates and ternary compounds are dealt with at length, whereas the question of colour, for example, receives somewhat old-fashioned and perfunctory notice, omitting entirely the ingenious and subtle suggestions of Saha (1930–31) and the work that followed them. The format, too, is not very attractive, with its cramped setting, which makes the otherwise valuable tables difficult to follow.

It is tempting to compare the outlooks displayed by these two books. The Cambridge view of crystal chemistry is something like this. Here are the 'things', and here is a copy of the rules according to which the game is to be played. It now rests with the players, and the degree of skill which they have achieved is of no mean order. The American approach is otherwise: chemistry as usually taught is not altogether satisfactory; let it therefore be impregnated with a new and active principle, but the way will be long and the wind cold.

A profound study of the solid state is a first-rate intellectual pursuit in either case. For Dr. Evans, however, it is—probably subconsciously—great fun: one doubts whether it is quite that for Dr. Stillwell. F. IAN G. RAWLINS.

SOME EASTERN AUSTRALIAN WILD FLOWERS

Wild Flowers of Australia
By Thistle Y. Harris. Pp. xviii+198+65 plates. (Sydney and London: Angus and Robertson, Ltd., 1938.) 8*s.* 6*d.*

AT a moderate computation, the flora of Australia contains some eleven thousand species of vascular plants. These are found over an area about twenty-five times the size of Great Britain and Ireland, in an island continent which extends through more than 28° of latitude. It is no easy task to select for illustration a fair example of such a flora. In spite of its title, the present book can scarcely be said to have done so. About ninety per cent of the plants figured and described in it come from the coastal district of New South Wales or the adjacent highlands. It is true that many of these same species do extend into Queensland, and a smaller number south into Victoria; but the representation of the floras of Tasmania or South Australia is slight. The small number of Western Australian plants included gives no useful impression of the peculiar flora of that State.

The author says that her book is an attempt to meet the demand for a popular guide to Australian wild flowers. No claim to completeness is made, but it is unfortunate that no space was found for any eucalypt and that not a grass nor a sedge is mentioned. Some of the figured species are uncommon plants, whilst others, quite as beautiful and far more widespread, are omitted.

The book is divided into two parts. The first contains illustrations of 248 species, reproduced by three-colour process and grouped in sixty-five plates. Although the individual blocks are small (2¼ in. × 1½ in.), in many cases the pictures are successful in giving a true impression of the form and colour of the plant illustrated. In other cases the artist has made the limit of the block a sort of Procrustean bed and taken unwarrantable liberties with the length of flower stalks to make the plant fit the picture. The result is a travesty of the plant, as in the figures of Brunonia, Dipodium, or *Drosera binata*. Much of the colour work is good and the figures of many of the Proteaceæ, Myrtaceæ and Epacridaceæ do give a real impression of the plants depicted. The blue tones have reproduced least satisfactorily; the figures of Cheiranthera and Stenochilus are quite misleading. For technical reasons in printing, the blocks on a plate have been grouped according to predominant colour, not affinity of the plants. This has led to a haphazard association of plants which, in some cases, might have been avoided. Each plate is accompanied by a popular description of the plants, their distribution in the different States and their flowering season. By some irritating mischance, only once does this account face the plate to which it refers. There are some inaccuracies: one in this section should be corrected. *Dipodium punctatum* is not a parasite, but a holosaprophytic orchid.

The second part gives a systematic account of the families with keys and a brief technical description of the species figured. As there have been inevitably so many omissions of the genera and species, these keys would be very misleading to a stranger trying to run down a plant. A visitor to the 'bush' near Sydney is as likely to find a Leucopogon, Woollsia or Monotoca as an Epacris; but there is no warning in the key to the Epacridaceæ that such genera exist. In any future edition, the derivation of the generic and specific names given in this part requires careful revision. One error cannot be passed. The Smith commemorated in the species *Zieria Smithii* was not "an Australian biochemist". Sir E. J. Smith deserves better of Australian botany than to be so forgotten. T. G. B. OSBORN.

NEW PROSPECTS IN ISOTOPE SEPARATION

By Prof. Hugh S. Taylor, F.R.S., Princeton University

THE identification of the heavy hydrogen isotope and its separation gave considerable impetus to the search for methods of bulk separation of the isotopes of other elements. Previous to this time, the experimental man of science had been content to demonstrate that displacements of normal isotope ratios could be secured by one or other method. Aston and Harkins had shown that these ratios could be changed by diffusion processes in the cases of neon and chlorine. Brönsted and Hevesy changed slightly the atomic weight of mercury by distillation methods. It was the separation of the hydrogen isotopes and the demonstration of their extraordinary utility in many problems of chemical, physical and biological interest that re-awakened the interest in more complete separations of other isotopic elements. The simultaneous advances in the study of the nucleus, by bombardment with swift-moving primary particles, enhanced the desire for individual isotopic species of the elements, at the same time that it provided an alternative tool for research in the form of artificially produced radioactive elements.

The successful separation of the hydrogen isotopes by electrolysis has not been extended to other elements. The separation factor is too low in the case of oxygen to make the method practicable, and the same is true for lithium. The use of a series of diffusion pump units, developed by Hertz, has permitted large changes in isotope concentrations to be secured, notably with hydrogen, neon and carbon. The separation was complete in the first two cases, and 50 per cent ^{13}C has been secured with methane as the diffusing gas. Minor concentrations of heavy nitrogen and oxygen have also been obtained. The principal objection to the method is the small amount of concentrated products which may thus be secured, since the pumps operate at not more than a few millimetres pressure. Capron and de Hemptinne were enabled to increase the speed of attainment and the yield of 50 per cent ^{13}C from methane by incorporating in the pump circuit, at the light end, a reservoir of methane in the form of gas adsorbed on silica gel at liquid air temperatures. For the concentration of oxygen, the most promising method developed hitherto has seemed to be the distillation column method as constructed by Pegram, Huffmann and Urey.

The most encouraging successor to the electrolytic separation of hydrogen proved to be the isotopic exchange reaction method developed by Urey and his colleagues. With this method, isotopic ^{15}N has been made available in large amounts of moderate concentrations and smaller amounts of highly concentrated heavy isotope. In this method, ammonia gas is exchanged countercurrent with ammonium ion in a column, the heavy nitrogen accumulating at the bottom. The success of this process makes 100 per cent ^{15}N available, at not too great cost, whenever required. The extension to heavy carbon is in progress, involving exchange between hydrogen cyanide gas and sodium cyanide liquors, by which exchange simultaneous separation of both carbon and nitrogen may be secured. The laboratory scale data seem as promising as those of nitrogen. Sulphur can be similarly treated with a greater separation factor than with carbon. Exchanges with zeolitic materials may be employed in the case of the ions of the alkali elements.

The mass spectrographic method can obviously be employed for the separation of charged ions, and this has been put to use in the preparation of the small amounts of the lithium isotopes necessary for nuclear and transmutation reactions. The development of high speed air-driven centrifuges, notably by Beams of the University of Virginia, has led to their use in isotope separation. Units are now in operation on liquids, with continuous feed and bleed. Marked displacements of the isotope ratio of chlorine in carbon tetrachloride have thus been secured. This method is most promising for not too large separations but in marked quantities. The separation depends only on the atomic weight difference and not on the mass ratio, and can thus be applied to liquids containing isotopes of high atomic weight as well as to the lighter isotopes. The method requires, however, expensive equipment and a slowly acquired technique.

From the point of view of general availability in the average laboratory, the newest method of isotope separation developed by Clusius and Dickel[1] is the most interesting, and of great promise for the general solution of the problem of separation of gaseous and liquid isotopic materials in quantity. Clusius combines the well-known thermal diffusion process, suggested by Chapman, with a thermal syphoning process by carrying out the separation in vertical tubes in the axis of which is a hot surface, the outside surface being kept cooled. The original form consisted of a heated wire placed concentrically in a cylindrical tube. In tubes of one metre length with a temperature gradient from centre to outside of 300–600°, it was shown that bromine in helium and carbon dioxide in hydrogen could be practically completely separated, the heavier gas concentrating at the bottom of the vertical column. With a three-metre tube, a four-fold concentration of oxygen in air was secured and a three-fold concentration of the heavy neon isotope. In the same tube a displacement of the chlorine isotopes in hydrogen chloride from 76 : 24 to 60 : 40 was secured in one operation. More recently[2] Clusius and Dickel announced the production in a tube of total length 36 metres, of 8 c.c. daily of hydrochloric acid of which more than 99 per cent of the chlorine was of mass 37. Simultaneously, at the top of the column two litres of hydrochloric acid ($Cl = 35{\cdot}147$) was produced, from one litre of which 25 c.c. of hydrochloric acid ($Cl = 35{\cdot}06$) could be produced. Further purification of this should, owing to the packing fraction of the element, give a chlorine of atomic weight just less than 35.

The method has been tested by W. Groth[3] on the separation of xenon isotopes in comparison with a 12-stage Hertz diffusion pump system which gives a displacement of 0·5 units in the atomic weight in 12 hours at 2 mm. pressure. The same displacement can be secured at atmospheric pressure in a 2·5-metre tube, 12 mm. wall diameter, heated down the centre by a tungsten wire at 1,000°. With a 5-mm. tube and a wire temperature of 1,650°, a displacement of 1·6 atomic weight units was secured. In a metre tube with a glass core heated internally, Brewer and Bramley[4] showed that a 27 per cent enrichment of ammonia at the bottom of the column with 50 : 50 methane (16) – ammonia (17) mixtures could be secured in fifteen minutes under favourable pressure and temperature gradient conditions.

The separation of the chlorine isotopes, successfully achieved by Clusius and Dickel, represents one of the most favourable cases for the operation of the thermal diffusion process. For, as Chapman showed, the separation is dependent on the product, C_1C_2, of the two fractions C_1 and C_2 of the mixture, respectively 0·76 and 0·24 in the cases of ^{35}Cl and ^{37}Cl. The separation of the carbon isotopes is much less favourable since the ratio ^{12}C to ^{13}C is 0·99 : 0·01.

Experiments conducted by G. G. Joris in the Princeton laboratories show, however, that even this mixture is capable of efficient resolution. In a column 1·5 metre long, with wall distance between hot and cold glass surfaces of 7·5 mm., a mean temperature of 400° K. and a temperature gradient of 450°, a separation factor $^{13}C : {}^{12}C$ (bottom) $\div$ $^{13}C : {}^{12}C$ (top) of 1·21 is secured in one hour. In three separate three-metre columns with varying dimensions of hot and cold surfaces and wall distances from 7·5 mm. to 10 mm., with the same temperature conditions, the separation factor rose to 2, but in longer time intervals up to 5 hours. The most recent data secured on a 12-metre iron tube, 2 cm. internal diameter, heated axially by a chromel wire, No. 16 gauge, gave a separation factor of 3 in 48 hours with a heating current of 6 amperes, and a separation factor of 20 in 48 hours with a heating current of 9 amperes. This latter represents a concentration of the normal isotopic fraction of 1·1 per cent ^{13}C to 2·1 per cent at the bottom of the column and a depletion to $\sim 0{\cdot}1$ per cent ^{13}C at the top of the column.

It is obvious that the maintenance of this separation factor will result in concentrations of upwards of 20 per cent ^{13}C at the bottom of the column when the normal ratio of 1·1 per cent ^{13}C is kept at the top of the column. Such experiments are in progress. In the 12-metre tube, 3·76 litres of gas at 20 cm. pressure at ordinary temperatures are employed, methane being the gas used for the separation. Experiments by Prof. T. Ri, in the smaller columns, with carbon dioxide – oxygen and nitrogen – ammonia have shown that the separation factor depends on composition variables, on the pressure (the factor shows, in agreement with a previous finding of Brewer and Bramley, a broad maximum in the region of 20–30 cm.) and most pronouncedly on the temperature gradient. This is obvious from the preceding data in the 12-metre column and also from data obtained with nitrogen – ammonia mixtures in the 1·5-metre column.

The theory of the thermal diffusion – thermal syphon process is complex. Two contributions are now available, one by Waldmann[5] and a paper by Furry, Jones and Onsager[6]. From Waldmann's paper the superiority of the process over straight thermal diffusion is measured by the ratio $0{\cdot}67\ h/d^*$ where h is the height of the column and d^* is of the order of magnitude of the distance between hot and cold surfaces. The convection therefore multiplies the thermal diffusion effect enormously in tall columns. The temperature gradient also plays a determining role in the same theory. That the process is also applicable to liquid separations is evident from data of Clusius and Dickel[2] with sodium chloride solutions, acetone – water mixtures, and light and heavy water. The same conclusion is reached from the data of H. Korsching and K. Wirtz[7] with *n*-hexane – carbon tetrachloride and benzene – chlorobenzene mixtures.

THE GAS INDUSTRY IN GREAT BRITAIN

WILLIAM MURDOCH died one hundred years ago and, at the annual meeting of the Institution of Gas Engineers on June 6 last, his position as founder of the gas industry received grateful commemoration in a Murdoch Centenary Lecture delivered by Dr. E. F. Armstrong. The lecture was only to a small extent biographical, although points of interest are recorded bringing out clearly the all-round quality of the man as a born engineer "of admirable inventive power and common sense genius", to quote the tribute of Nasmyth. It was made the occasion for the preparation of a reasoned history of the gas industry in Great Britain in the small compass of sixty-seven pages, brief but packed with information concerning the highways and some of the byways on which the industry has travelled in time.

Although Murdoch is accorded his rightful place, proper acknowledgment is made of other founders of the industry, such as Samuel Clegg, whose "mark on its history is second only to that of Murdoch" and who became engineer of the Chartered Gas Company in 1813 and had "practically single-handed to give a public service supply. Thus, when a few gas lamps were first installed on Westminster Bridge, the lamplighters refused to handle them so that he had to go round with his ladder and light them himself". Scepticism on the practicability and safety of public lighting with gas was very general and was shared even by men of the scientific calibre of Humphry Davy. Winsor also is not forgotten, a man of little technical knowledge but a fervent enthusiast, described as the "exploiter, propagandist and undaunted impresario of our Industry, to whom must be given the credit for the idea of widespread illumination from a single source".

The year 1839 was unusually eventful and, under the heading "A Century Ago", Dr. Armstrong sketches a background of contemporary happenings. In 1839 the first railway train left Euston on the first stage of the new London to Birmingham railway, the *British Queen* made the Atlantic crossing under steam alone, "Nicholas Nickleby" was published and people were reading Carlyle's "French Revolution", issued two years earlier, and the *Sunday Times* for January 13 reported that "On Thursday evening Hounslow was lighted up for the first time with gas supplied from the gasworks at Brentford. There are 18 lights." Both steam and gas, two great industrial users of coal, one for power and the other for lighting, had become more or less established by this time, and in an appendix Dr. Armstrong gives a list of ninety gas companies established by Act of Parliament up to 1839.

A patent was granted in 1819 to David Gordon for compressing gas and supplying it in copper cylinders under a pressure of 30 atmospheres, and such 'portable gas' was used at the Royal Institution until 1834, when it was replaced by coal-gas. "Historically", Dr. Armstrong points out, "the Portable Gas Company must always be associated with the discovery of benzene which Faraday separated in 1825 by distillation of the condensed oil gas liquor that collected in the vessels used by the Company."

The primary use of gas for more than a century was for lighting, and the story of the development of the apparatus in which it was burned has been well told by Dean Chandler. The invention of the incandescent mantle by Welsbach, first shown to the public in 1887, came at the right moment because "the electric bulb was introduced only a year or two earlier and started a new era of competition with gas-lighting". Dr. Armstrong quotes interesting figures for public lighting by gas in the area supplied by the South Metropolitan Gas Company. In 1899, with flat-flame burners, the candle-power per cubic foot of gas consumed per hour was 2·5; in 1902, with upright incandescent burners, 14·0; and in 1938, when 70·6 miles of lighting by high-pressure lamps was included, the figure had risen to 43·0.

As the gas industry in Great Britain developed and monopoly of supply was granted to each company in its own area, the absence of competition and the technical possibility of producing a larger volume of leaner gas through the use of fireclay retorts (instead of iron) at a higher temperature brought into prominence the necessity for a rigid control of gas quality. For this purpose the City of London Gas Act of 1868 appointed a body of three competent and impartial persons known as the 'gas referees' to prescribe apparatus and methods to be used in the testing of gas. This arrangement continued until a few months ago when, as Dr. Armstrong regretfully remarks, "The disappearance of the Gas Referees, as the result of the Gas Undertakings Act of 1934, which has transferred their duties to the Board of Trade, has meant the loss of a contact with leaders in the scientific world to which the Gas Industry has attached great value." This is none the less true although, since the passing of the Gas Regulation Act of 1920, calorific value has quite rightly taken the place of illuminating power as the criterion of quality throughout Great Britain.

It was recognized early in the history of the gas industry that the presence of sulphur compounds in gas was very objectionable and Clegg tried as early as 1805 the device of putting lime into the tank of the gas-holder for purification. Dr. Armstrong points out that eleven different processes were in operation in the gas works of the Metropolis in 1856–57. The complete removal of sulphuretted hydrogen by iron oxide, revivified by air, has become standard practice, but the residual sulphur compounds, amounting usually to some 20–30 grains per 100 c. ft. still provide an incentive to research, although oil-washing for benzole and the Carpenter-Evans catalytic process have both been applied successfully to lower this figure.

The usefulness of gas as a fuel for heating purposes and its virtues were "extolled by the indefatigable Winsor". Alfred King invented a gas-cooking-stove so early as 1830, and in 1872 the Salisbury Gas Company commenced hiring cookers to consumers. The earliest attempts were simply solid fuel ovens with gas burners inserted, and Dr. Armstrong traces the development to the cooker of to-day with enamelled finish, thermostatic control, safety-taps, quick-boiling burners and other useful adjuncts. By 1850 there were a number of gas fires in use, these consisting merely of lumps of pumice or other incombustible matter in a coal-grate with a gas-burner below. It was not until between 1904 and 1908 that the gas-fire radiant was introduced, and a new impetus was given to efficiency of design by the experimental study of the gas-fire by the newly formed Joint Research Committee of the Institution of Gas Engineers and the University of Leeds. Modern design is directed to high radiant efficiency combined with a distribution of heat making for the maximum of comfort. Ventilation too has been studied in detail. The rise in radiant efficiency is given by Dr. Armstrong as from 29 per cent on the gross calorific value in 1909 to 45 per cent in 1939 on the same basis.

It is not possible to make more than a mention of many other matters which are included in the lecture, some gratifying curiosity and others a deeper interest; for example, the possibilities of a greatly increased load for industrial heating offer an excellent example, and the whole range of secondary products, such as coke, tar and ammoniacal liquor. The modification of the retort from iron to fire-clay, horizontal to vertical, intermittent to continuous, and the whole subject of water-gas must be left, as well as an interesting page on co-partnership and a synopsis of gas legislation. There is, too, a suggestive final chapter entitled "The Present and Future of Gas", indicating possible lines of advance and insisting on the gas industry's taking a pride in attracting the best men into its ranks both as whole-time workers and as advisers.

JOHN W. COBB.

CERCOSPORA LEAF SPOT DISEASE OF BANANAS

By DR. C. W. WARDLAW, IMPERIAL COLLEGE OF TROPICAL AGRICULTURE, TRINIDAD

THOUGH widely distributed in the Indo-Malayan and Australian regions and known to mycologists since 1902, the leaf spot disease of bananas caused by *Cercospora musæ* Zimm. (also known as Sigatoka disease) was not recorded in the western tropics until 1934[1]. It is not known precisely how or when this malady was introduced into the Caribbean region, or whether its spread took place from one or several foci of infection; but during the brief period of two to three years from its first recognition in Trinidad it had appeared with epidemic intensity in many of the islands and on the mainland of Central and South America, and by its destructive effects on plantations showed itself to be a disease of first-class economic importance.

Briefly, the disease manifests itself as a profuse spotting of leaves; later, the tissue around the spots begins to die rapidly and large, coalescing dead patches appear, so that in severe infections the leaf may be more or less completely destroyed (Figs. 1 and 2). Bunches on affected plants show slow or arrested growth and behave abnormally during development and subsequent ripening. Where the economic situation permits, the disease is being fought by dusting and spraying with various copper-containing fungicides.

SPREAD AND INTENSIFICATION

Information on the spread and intensification of a disease from an initial infection to the stage where it has assumed epidemic proportions is not always available to the investigator. In Trinidad, however, it has been possible to follow the progress of Cercospora leaf disease through its several phases. The disease was first observed in the Maqueripe district in north-west Trinidad in a small, new plantation of Giant Governor bananas, the planting material for which

Fig. 1.

SEVERE SPOTTING OF BANANA LEAVES BY *Cercospora musae* Zimm.

(underground rhizomes, bulbs, etc.) had been obtained from scattered plants in the southern part of the island in January 1932. Leaf spotting became conspicuous towards the end of 1933, and plants of the Dwarf Cavendish variety in immediate proximity also became infected, though in a less severe form, some time later.

During frequent inspections at the beginning of 1934, Cercospora leaf spot was not observed anywhere in the Maqueripe district except in this one area, the Giant Governor plot being the centre of infection. A thorough stripping and burning of all diseased leaves was undertaken; but this did not halt the progress of the disease, and by the end of 1934 it became evident that adjacent Gros Michel blocks planted in 1932–33 had become infected. An island survey undertaken about this time showed that the disease was also becoming generally distributed, but whether only from Maqueripe or from several foci of infection is not known.

At this stage, the Gros Michel blocks at Maqueripe, though generally infected, showed little diminution in productiveness. The general mycological observation made during 1934–35 was that the older the stand of plants, the more intensive was the infection; but premature ripening of bunches on the plant, as previously recorded by Australian workers, was nowhere observed. During 1936 production was seriously affected: plants at all stages of development were severely spotted, many bunches showed slow or arrested development and an increasing number of commercial bunches was spoilt by premature ripening. During an inspection in January 1937, practically every bunch of export size showed this symptom. The intensification of infection to the point where premature ripening of bunches becomes general is the most serious economic aspect of this disease.

PHYSIOLOGICAL ASPECTS

On physiological grounds, several aspects of the disease require comment. It is known from detailed studies undertaken by Stahel in Suriname that leaves can only be infected when quite young, that is, at the time of unrolling or soon after, the pathogen entering by way of the stomata. Penetration of the tissues takes place slowly, typical lesions requiring from three to four weeks for development. Although *C. musae* may cause serious losses on a wide range of soil types, the severity of spotting and rapidity of leaf destruction appear to be associated with certain adverse growth conditions, unfavourable water relations (as in water-logged clay soils, light soils subject to rapid drying out, etc.) being important. The debility and premature ageing of leaf tissues, known in some instances to be determined by unfavourable water relations, may be envisaged as standing in somewhat the same relation to Cercospora leaf disease as does the premature senescence of fruits to the early development of latent infections. It is relevant to note that in resistant varieties only the oldest leaves normally become spotted. But where such varieties are being grown under conditions which make for extreme physiological drought, some of the younger leaves may also show the development of typical Cercospora lesions.

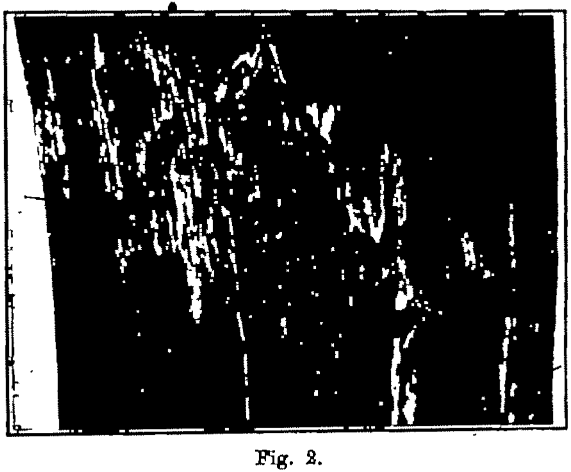

Fig. 2.

SEVERE SPOTTING OF LEAVES BY *C. musae* Zimm. FOLLOWED BY THE DESTRUCTION OF CONSIDERABLE AREAS OF LEAF TISSUE.

Severe leaf spotting is accompanied by the development of a buff to pale ochraceous salmon colour in the pulp. A less conspicuous but easily observable symptom is the presence of a characteristic pale bluish discoloration of some of the vascular strands of the true stem. These contain vessels in which various pathological symptoms, including the production of tyloses and the collapse of vessels, have been or are being induced as a result of the diseased condition of the leaves. In severely diseased plants, where the bunch is still quite small and immature, this symptom can also be observed. As the development of the bunch proceeds directly from the storage rhizome and indirectly from the leaves, it may be suggested that, as a result of severe leaf disease, the rhizome is itself to some extent in a physiologically unbalanced condition or affected by toxic fungal secretions. If support for this view can be obtained, it will have an important bearing on the elucidation of the progressive intensification of infections described above, and of other aspects of the disease.

EFFECT ON COMMERCIAL FRUIT

Severe attacks of Cercospora leaf disease are accompanied by a premature ripening of bunches while still attached to the plant. When the disease is less severe, apparently normal green bunches may be harvested, but during the 30–36 hours that elapse before the bunches are charged into the holds, individual fruits or a majority of the fruits of affected bunches may become soft and yellowish. In still less severe infections, affected bunches may escape detection at the wharfside, but may become soft and coloured during the period of refrigerated transport. Bunches which are only slightly affected may behave as approximately normal fruit.

In bulk storage trials, details of which are given elsewhere[4], it has been conclusively demonstrated that when bunches harvested at "¾-full" (English) grade from a plantation showing what might be described as an intermediate intensity of Cercospora leaf disease, are held at 53° F. for fifteen days with subsequent ripening at 68° F., evidence of abnormal storage behaviour can be observed. Affected fruit is characterized by pulp or a more or less well-marked buff colour, it tends to ripen prematurely, to develop 'chilling' symptoms during the period of refrigerated transport, and to ripen with undesirable rapidity on removal to a higher temperature. Flavour and aroma are also affected. So far nothing is known of the biochemical nature of the abnormalities present in affected fruit at harvesting, but after cold storage it may be expected to share some of the undesirable features of fruit which has been chilled. 'Cercospora bunches' ripened at tropical temperatures frequently show a profuse development of anthracnose spots (*Glœosporium musarum*) on attaining to the 'eating ripe' condition.

The effect of Cercospora leaf disease on fruit physiology is twofold: (i) ripening abnormalities are introduced; and (ii) bunches tend to remain of small size; hence, as fruit may actually be considerably more mature than is indicated by its appearance, further departures from the normal storage behaviour for that grade may be anticipated.

SPECIFIC AND VARIETAL SUSCEPTIBILITY OF BANANAS

Since the first recognition of this disease, various commercial varieties, including the Gros Michel, Dwarf Cavendish, Congo and Giant Governor have proved highly susceptible under plantation conditions. When plants of the Imperial College Hybrid, I.C.2 (derived from *M. acuminata*, a wild seeded species as male parent, and the Gros Michel as female parent) were established in close proximity to severely affected Gros Michel plants, it was observed that spotting only occurred in a mild form on the oldest, senile leaves. This variety, in brief, apparently possesses considerable inherent resistance to infection or exploitation by *Cercospora musæ*—an observation which again directs attention to the importance of attempting to secure new commercial types of bananas by appropriate hybridization studies.

By way of amplifying knowledge of the relation between hereditary constitution and susceptibility to Cercospora leaf disease, a survey was made by Prof. E. E. Cheesman and the writer of the very considerable collection of types, species and hybrids available for study at the Imperial College of Tropical Agriculture[5]. Three definite conditions have been recognized: of the twenty-two types and two sub-types, thirteen are definitely susceptible, eight are highly resistant or immune, and three are *mildly* susceptible, spotting as a rule occurring only on the oldest leaf of fully grown plants, or plants bearing bunches. Among the species collection, a high degree of resistance is the rule: *M. acuminata* Colla (clone *A*), *M. balbisiana* Colla (clone Ceylon), *M. textilis* Nee, *M. ornata* Roxb., Pisang Lilan, undetermined species from Annam and Burma have consistently remained quite free from Cercospora spotting although growing in close proximity to severely infected stools of susceptible varieties. Among a third collection comprising sixteen different clones, referred to *M. balbisiana* (*M. sapientum* L. *senus* Roxb.) no spotting has occurred. In the collection of Imperial College hybrids, most of the plants, with some interesting exceptions, are quite free from leaf spotting. Among a large number of other hybrids in which hereditary characters from parental wild species are prominent, a noticeable absence of leaf spotting is again the rule.

In both the species and hybrid collections it is to be noted that infections described as *mild* are all characteristically of one kind, spotting occurring only on the oldest leaf. Recent field observation on plots of I.C.2, located in different parts of the island, indicate that where Cercospora infections occur, they are invariably of the mild type.

The hybrids mentioned above have been raised in the course of a breeding programme directed primarily towards the control of Panama disease (*Fusarium oxysporum cubense*) and their resistance to an entirely different malady is as interesting as it is potentially important. It may also be pointed out that the eight varieties highly resistant to Cercospora are all likewise highly resistant to Panama disease. The numerous qualities required of a commercial banana remain the same whether it is to be bred resistant to a wilt or to a leaf spot. Evidence has accumulated to show that combining those qualities in a single plant is the real problem of banana breeding, rather than disease resistance alone. The conclusion has already been drawn that the greatest hope of obtaining a good export banana resistant to Panama disease lies in breeding from Gros Michel with appropriate wild species. It follows that the best hope of obtaining a good export banana resistant to Cercospora leaf spot lies in the same direction[5].

OBITUARY

Dr. E. T. S. Appleyard

THE tragic death of Dr. E. T. S. Appleyard through injuries caused by a fall came as a great shock to his many friends. He was born in 1904, the son of Edgar Snowden and Elizabeth Appleyard of Huddersfield. He received his school education at Almondbury Grammar School and entered Cambridge as a scholar of King's College. Taking a first class in physics in the Natural Science Tripos, he spent several years on research in the Cavendish Laboratory. In 1929 he was appointed to a George Wills research associateship in the Wills Laboratory at Bristol, a post which he held until his death. During the tenure of this post he was awarded a Rockefeller fellowship for the session 1931–32 in the University of Chicago.

Appleyard's first research in the Cavendish Laboratory was on the polarization of the light emitted from atoms bombarded by a directed beam of electrons, and this was afterwards extended to the case of excitation by positive ions.

Following upon a few minor papers in spectroscopy in his earlier years at Bristol, Appleyard embarked upon a new field to which he made important contributions. With Lovell (*Proc. Roy. Soc.*, 1936, 1937) he investigated the nature of thin metallic films of the alkali metals evaporated on to a cooled surface *in vacuo*, by measuring their electrical conductivity under varying conditions. This work threw an entirely new light on the subject and cleared up many previous discrepancies in the literature. He followed this with similar work on mercury films, and with the co-operation of the Royal Society Mond Laboratory and the collaboration of Bristow, Misener and London, he extended the investigation to the superconducting state. A summary of his results on the variation of magnetic field penetration with temperature has already appeared in these columns (143, 433 ; 1939), and his last active work was to complete the paper describing the investigation in detail. Its consequences are of much significance and the results have already created considerable interest.

Appleyard was a very able physicist with an acute and critical mind. His wide knowledge, not confined to his own fields of work, made him an invaluable member of a research laboratory. In addition to research he took his share in the teaching and supervision of Part II honours students at Bristol, a number of whom have stated how much they appreciated the thought and time he gave to their interests. Indeed his willingness to be of assistance to everyone in the laboratory, academic and laboratory staff alike, and his desire to ensure that the fullest credit was given to all who helped him in his work, was one of his most lovable characteristics.

Appleyard experienced great pleasure, which his colleagues shared, on the success of his recent experiments on superconductivity, and a fruitful field of research for some years on similar lines seemed to be open to him. It must now be left to others to carry it on. He will be sadly missed. A. M. TYNDALL.

WE regret to announce the following deaths :

Dame Maria Ogilvie Gordon, known for her work on the geology of South Tyrol, on June 24.

Sir Frederick Hobday, C.M.G., honorary veterinary surgeon to the King, formerly principal of the Royal Veterinary College, on June 24, aged sixty-nine years.

Dr. Witmer Stone, emeritus director of the Academy of Natural Sciences of Philadelphia, on May 23, aged seventy-two years.

Dr. Yojiro Wakiya, formerly director of the Fisheries Institute, Fusan, Chosen, on April 21, aged sixty-seven years.

NEWS AND VIEWS

The Royal Visit to America

THEIR MAJESTIES were greeted on their return to England on June 22 and again on their drive to, and from, the Guildhall in the City of London on the following day with enthusiasm which needed no pageantry, no ceremonial, to quicken its sense of the significance of the events of the brief period which have elapsed since the King and Queen sailed for Canada on May 6. King George and his Consort were being hailed as conquerors—conquerors of a continent—no less certainly than were those of their predecessors, who in days gone by had passed through Temple Bar to celebrate a victory in the capital city. In this enthusiastic, but intimate, greeting of King and Queen there was a deep and strong undercurrent of loyal gratitude to them that in their journey from one end to the other of the vast Dominion of Canada, and no less in their visit to its great neighbour, the United States of America, their Majesties had so borne themselves that personal devotion to those wearing the Crown and a spirit of kindly hospitality to honoured guests had been transmuted to a deeper consciousness of the common devotion of all, President and citizen, Sovereign and subject alike, to the ideals of liberty and justice which transcend birth, creed and the barriers of national division in a supreme loyalty to the cause of humanity. In all the ceremonies and incidents of the Royal tour which, as His Majesty said at the Guildhall with a homely but happy touch of common interests, have been made "familiar . . . through the daily press, the news reels, and the Broadcasting Corporations", none was so deeply charged with emotion, none so moving to those gifted with historical imagination, as the simple scene in which King George laid a wreath upon the tomb of George Washington. This act of homage epitomizes as a symbol a memorable episode in the history of the British Commonwealth of Nations no less surely than His Majesty's impression of his experience, summed up in the memorable words "the strength of human feeling is still the most potent of all the forces affecting world affairs".

Pilgrim Trust Lecture

THE Pilgrim Trust Lectures, administered jointly by the Royal Society and the U.S. National Academy of Sciences, were inaugurated last December by a notable lecture delivered by Dr. Irving Langmuir in the theatre of the Royal Institution, London. The selection of the lecturer for the second of the series was in the hands of the Royal Society, which decided, most appropriately, to send its president, Sir William Bragg, as the ambassador of science in Great Britain to the United States. Sir William visited the United States during the spring, and on April 24, in the course of the annual meeting at Washington of the National Academy of Sciences, delivered the second Pilgrim Trust Lecture, which appears on p. 21 of this issue of NATURE. The effect of science upon social conditions formed the theme of Sir William's address, which he illustrated by dipping into the history of the Royal Society. Starting as a body of 'virtuosi' who met for discussion and experiment about the middle of the seventeenth century, the Royal Society early became concerned in problems of interest to a wider circle and to the State. Inquiries submitted to correspondents, their reports, and papers read before the Society, illustrate the effects of science upon society and conversely, of the circumstances of the times upon scientific investigations. Sir William leads up to an eloquent plea for the earnest consideration of current affairs in the spirit of science, which links up with the efforts of the Division for Social and International Relations of Science of the British Association; the Manchester meeting of the latter referred to on p. 1 of this issue deals specifically with some social aspects of scientific research, while Sir William points the moral on the wider issue.

Mr. M. G. Evans

THE chair of physical chemistry in the University of Leeds which fell vacant by the death of Prof. H. M. Dawson in February last, has been filled as from October 1 by the appointment of Mr. M. G. Evans, lecturer in chemistry in the University of Manchester. Born on December 2, 1904, he was educated at Leigh Grammar School and passed through the University of Manchester, where he was a pupil of Prof. A. Lapworth. While Prof. Hugh S. Taylor of Princeton was staying as a visitor for one term at the University of Manchester in 1931, Mr. Evans joined him in research on adsorption, and he renewed this connexion later by working for one year in the Frick Chemical Laboratory in Princeton, where he was closely associated with Prof. Henry Eyring. Since his return to Manchester in 1934, Mr. Evans has steadily developed his theoretical investigations on the mechanism of chemical reactions. During this time he has richly contributed to the fund of ideas which, it is the hope of the younger school of physical chemistry, promises to form a pattern for the understanding of at least the simpler types of reactions. Though Mr. Evans's principal contributions to science are in the theoretical field, he also took active interest in the experimental work carried on in Manchester. His appointment to one of the three chairs in the Department of Chemistry in Leeds is a significant recognition of the part which the new theories originating from quantum mechanics have to play in the life of chemistry to-day.

Dr. J. B. Speakman

THE appointment of Dr. J. B. Speakman to the chair of textile industries of the University of Leeds will afford pleasure to the many admirers of his work on the structure and properties of the wool fibre. Dr. Speakman is a graduate and D.Sc. of the University of Manchester, where, except for a period of war service, he spent the years 1915–1920. His next three years were passed at Eton with Prof. R. Whytlaw-Gray, carrying out research on aerosols for the Chemical Warfare Committee. Since 1925 he has been in charge of the Textile Chemistry Laboratory of the University of Leeds, where he was appointed lecturer in 1925 and reader in 1937. Dr. Speakman has been awarded the Warner Memorial Medal of the Textile Institute, and three times he has been the recipient of the Research Medal of the Worshipful Company of Dyers. He has also served for a dozen years on the council of the Textile Institute, and on the Publications Committees of the Textile Institute and the Society of Dyers and Colourists. Under his direction, the Leeds Textile Chemistry Laboratory has attained a high and well-deserved reputation, and his new appointment will undoubtedly lead to still wider successes in his chosen field.

Dr. R. G. S. Hudson

DR. R. G. S. HUDSON has been appointed to succeed Prof. A. Gilligan as professor of geology in the University of Leeds. Dr. Hudson studied geology at University College, London, under Prof. E. J. Garwood. He later joined the staff of the Geological Department at University College and commenced research on the fauna of the Yoredale Series. He continued his interest in Carboniferous stratigraphy after his appointment in 1922 to the geological staff of the University of Leeds. The greater part of his work has dealt with the Dinantian and Namurian of Yorkshire especially with the relation between the various facies and faunal assemblages. He early demonstrated the unconformable junction between the Lower and Upper Carboniferous of Yorkshire; later, with Dr. G. H. Mitchell he described the geology of the Skipton anticline, and with the aid of various grants put down a boring in that area to the base of the Carboniferous. He has devoted attention to the Variscan orogeny and its control of sedimentation. His interest in the fauna of the Carboniferous has resulted in the description of new genera and species of corals such as Rylstonia, Rhopalolasma, and various species of Orionastraea. In 1931, Dr. Hudson was awarded the Wollaston Fund of the Geological Society and has served on the Council of that society. He has also been secretary of various committees of Section C, British Association, and is now joint secretary of that section. Dr. Hudson has taken considerable part in the organization of the geological societies in Yorkshire, and for some years has been editor of the *Proceedings of the Yorkshire Geological Society* and the *Transactions of the Leeds Geological Society*.

Imperial Cancer Research Fund: New Laboratories

THE new laboratories of the Imperial Cancer Research Fund were opened on June 27 (see also p. 41). Sir Humphry Rolleston, chairman of the Executive Committee, read a message of regret from Lord Halifax, president of the Fund, who at the last moment had found himself unable to attend. Lord Halifax said that all would appreciate that at the present time he is even more than usually subject to sudden and unavoidable calls on his time and that although he ought not, perhaps, to have agreed to open the new laboratories he had been particularly anxious to do so. Lord Halifax sent the notes which he had prepared for his speech, in which he reviewed the history of the foundation of the Fund and its progress. He referred to the many famous men, including Lord Lister, A. J. Balfour and Joseph Chamberlain, who helped the Fund and mentioned the policy of collaboration with all organizations at home and abroad which has been followed throughout the thirty-seven years of the Fund's existence. An address on "Scientific Aspects of Cancer Research" was delivered by Sir Frederick Gowland Hopkins, whose theme was the importance of laboratory effort in cancer research. He expressed his own faith that each increase in accommodation provided for skilled laboratory effort has never failed to be justified by its results. Sir Frederick described the distinguished past of the Fund and stated his confidence in a future of continued and eminent success. A vote of thanks to Sir Frederick was proposed by Sir Robert Hutchison, president of the Royal College of Physicians and seconded by Mr. Hugh Lett, president of the Royal College of Surgeons.

THE laboratories, designed by Messrs. Lanchester and Lodge, occupy an open position on the Ridgeway at Mill Hill. The three-storied main building is built in T-form with a central staircase; the corridors, as a result, are short and well-lighted. A goods lift serves one wing which is devoted mainly to animal rooms, stores and service rooms. The library, offices, one large laboratory, a room for X-ray equipment, centrifuge room, workshops and stores are on the ground floor. The first floor comprises a large chemical laboratory with a smaller laboratory adjoining, five other private laboratories, photographic room, sterilizing room and animal rooms. The Director's office and laboratory are on the second floor, where there are three other laboratories, operating room, histological room and animal rooms. There is a cold room in the basement. The laboratories vary in size; some are suitable for one worker using simple equipment; others can accommodate two or three workers or bulky apparatus. Most of the rooms have one high and one low bench each with a sink supplied with mains pressure water and hot water; gas and 5 and 10 amp. electric points are provided. The natural lighting, by large windows, is notably good. Artificial light is supplied by central pendants and supplemented, wherever required, by Anglepoise table lamps. Elaboration of structure and equipment has been avoided in favour of adaptability to varied needs. A detached animal house is designed for work with the larger animals; provision is made for the maintenance of fowls and the normal stock of rabbits and guinea pigs. Other animals, as required, are accommodated in out-houses. There are six acres of land available for pens, grazing and the cultivation of food crops for animals.

The Decline of Population

A DEBATE on the prospective decline of population took place in the House of Lords on June 21. Lord Samuel pointed out that whereas the number of live births per 1,000 women of child-bearing age was 129·8 in 1891, at the census of 1931 it had fallen to 64·3, that is, almost exactly half in the forty-year period. In the earlier period one out of every four married women between the ages of fifteen and forty-five years gave birth to a child in any particular year, while in 1931 this was only true of one in eight. Counterbalancing effects, the fall in the death-rate and the change from emigration to an inward movement of people, was far from equalling this decline in the birth-rate. He advocated family allowances as a means of diminishing the cause and desire for small families. Other measures suggested were housing estates for larger families and removal of the marriage bar in certain occupations such as bank clerks and women teachers. He advised the appointment of a Royal Commission to inquire into the whole question. Lord Snell said that the real problem is qualitative rather than quantitative and that the question of age proportion is most important. Lord Dawson of Penn said the prospective fall in population is too great even if we have regard to quality, as the country has failed to reproduce itself since 1925 and to-day 100 mothers only produce 76 girl babies or future mothers. Contraception is a specialized example of man's gradual control of natural sources and is spreading to all classes and creeds. It should be seen that parents willing to bear their quota of children should not be penalized. In tenement blocks there should be crèches, nursery schools and other necessities, and the health services should be linked up into a connected whole.

LORD STAMP said there is little popular apprehension on this subject because we are still living under the delusion of continual expansion. He pressed for a quinquennial census to provide the necessary information for a Commission. Boys between the ages of thirteen and eighteen years in England and Wales in 1938 numbered 2,100,000. In seven years this will fall to 1,787,000. The effect of this tendency is already being felt in schools. The Bishop of Norwich remarked that his predecessor a century ago had thirty-seven children while that Bishop's two brothers each had thirty-two children. Households of the better stock now have small families, for one reason, because of the necessity for domestic help in rearing a family. Lord Derwent said family allowances would be inadequate without propaganda, and that the birth-rates of France and Italy continue to decline. This is principally from incertitude regarding the future. The Archbishop of York said that while the older men who have been out of work prefer to get back to work even if their wages amount to less than their relief, this is by no means true of the younger men. They should ensure in some way that a man in work always obtained more than a man without work. Lord Templemore put forward the view that some forecasts anticipate an earlier decline of population than appears justified. For the first time since 1873, the birth-rate began to rise in 1934 and this has continued for the last five years. But too great value should not be placed on that. As regards family allowances, public opinion has not yet crystallized. The Population Statistics Act, 1938, would supply information which should throw light on the incidence of fertility in different sections of the population.

Students and Military Training

THE adoption in Great Britain of the principle of conscription and the calling up for registration of youths between the ages of twenty and twenty-one years for a period of military service has raised the question of the position of university students. As regards those proceeding to universities after October next, Mr. E. Brown, Minister of Labour, stated in the House of Commons on June 22, that at a meeting held under the auspices of the Ministry between representatives of the Committee of Vice-Chancellors and Headmasters, together with representatives of the departments concerned, it was agreed unanimously to recommend that such boys should be given the option of postponing or anticipating their liability to undergo military training. Mr. Brown said he intended "to put this agreed conclusion into operation, subject to reviewing the position in twelve months' time in the light of experience, when I propose again to seek the advice and assistance of the representatives of the universities and the schools". He also agreed to bear in mind the further recommendation that those under the age of eighteen years on January 1 of the year in which they wish to take their training should not be allowed to anticipate their military service.

Biological Expedition to Jamaica

A LARGE expedition is leaving the University of Cambridge for Jamaica this summer. It is financed by the Royal Society, the Royal Geographical Society, Mr. J. A. Steers, Gonville and Caius and St. Catharine's Colleges, Cambridge, and the Universities of Cambridge, Manchester and Sheffield. The members of the expedition are Dr. V. J. Chapman, the leader, university demonstrator in botany, Cambridge; Dr. H. Hamshaw Thomas, reader in plant morphology, Cambridge; Mr. J. A. Steers, lecturer in geography, Cambridge; Mr. J. S. Colman, lecturer in zoology in the University of Sheffield; Mr. W. R. Philipson, of the British Museum (botany); Mr. K. R. Sporne, of Downing College; Mr. J. Lofthouse and Mr. D. J. Crisp, both of St. Catharine's College. The main party is proposing to examine shore-line development in relation to the formation of coral reefs and cays and also to the salt ponds, and it is intended to make a comparison of the cays and the mode of their formation with similar structures in the Great Barrier Reef. This will be facilitated by the presence of two members of the Great Barrier Reef Expedition—Mr. Steers and Mr. Colman. Dr. Chapman will examine the botanical side of this problem, and is intending to devote particular attention to the mangroves. A party consisting of Dr. Thomas, Mr. Philipson and Mr. Sporne is going to spend a month in the rain forest where each will carry out research on his own problems: Dr. Thomas working on the Pteridophyta, Mr. Philipson collecting, because he is one of those appointed to complete the late Dr. Rendle's "Flora of Jamaica", and Mr. Sporne investigating flower morphology. The whole expedition will return at the beginning of October with the exception of Mr. Philipson, who will stay on for a few more months.

Earthquake on the Gold Coast

EARTH tremors shook the whole district of the Gold Coast, Ashanti, Dahomey and Western Nigeria in West Africa from about 7.10 p.m. on June 22 to 4 a.m. on June 23. It is not yet clear whether there were several shocks of approximately equal dimensions from one or several closely situated epicentres, or whether there was one large earthquake with precursors and aftershocks. With the evidence available at the moment, the latter appears to be the most probable as the greatest impact of the earthquake was felt at Accra (5° 30′ N., 0° 10′ W.), Cape Coast (5° 5′ N., 1° 0′ W.), and Sekondi (4° 53′ N., 1° 48′ W.) at 7.15 p.m. on June 22. If the intensity of the shock was the same at each of these three places, as the immediately available evidence seems to indicate, then the epicentre was near 5° N., 1° W. and the focus rather below normal, or it was, say, 3·5° N., 1° W. in the Gulf of Guinea and depth of focus normal. Further evidence from the area, but more particularly the evidence of seismograms, will decide this. Many public buildings, banks, offices and native houses in the area have been damaged or destroyed, killing seventeen people at Accra, twenty-nine at Cape Coast and twenty at Sekondi, besides injuring several others. At Accra the electric lighting system was interrupted, but this was quickly remedied. An earthquake of these dimensions is an exceptionally rare occurrence, if not unknown, near Accra, and according to recent catalogues of epicentres there is no active epicentre anywhere near the present one. It is unfortunate that there are no seismographs situated nearer the probable epicentre than Algiers, Johannesberg, Cape Town and Nairobi, though the shock appears to have been sufficiently intense to have been registered at these, and by seismographs at even greater epicentral distances.

Entomological Control of Lantana

THE rapid spread of Lantana, a garden escape, in Northern Queensland has brought it amongst the serious weed pests for which the Council for Scientific and Industrial Research, Australia, is seeking methods of control. In 1935 studies of *Teleonemia lantanae* were commenced in Fiji, where this bug had been introduced from Mexico, its native home, by way of Hawaii. As it proved harmless to any Australian plants of economic importance, it was established under quarantine conditions in Canberra in 1936. The first liberations were made late in that year in the Northern Rivers area of New South Wales, and afterwards near Atherton in Queensland, and at Rockhampton. Disappointment followed; the bugs seemed to have disappeared, until in April of this year they were reported in the Atherton district in enormous numbers over an area of some twenty-four acres. Leaves were falling from the Lantana bushes, flowers had been destroyed and in some instances up to two feet of the ends of branches had been killed as the result of the bug feeding on them. At Rockhampton also there are signs of establishment. Undue optimism is to be deprecated, and it is unlikely that similar success will be attained to that of Cactoblastis on prickly pear. It still remains to be seen whether Teleonemia can maintain itself in large numbers and whether continuous defoliation will destroy Lantana; nevertheless, the outlook is promising.

Exhibition of New Textile Fibres

AN exhibition of new textile fibres has been arranged at the Science Museum, South Kensington, and will be opened on July 3 for two months. To-day fibres possessing many of the properties of natural wool are manufactured from skimmed milk. The exhibit illustrating the stages in the manufacture of casein yarn includes several examples of fabrics, woven on worsted machinery. Another group of exhibits includes yarns and materials as produced by the viscose and cellulose acetate methods. These are generally termed rayon or 'artificial silk'. By modification of the spinning processes it is now possible to manufacture exceptionally strong yarns of this material, and some of the applications are illustrated by such articles as a section of a motor tyre showing the cord reinforcement, 'doped' aeroplane fabric, fine gauge hose, sail cloth, etc. An interesting American exhibit shows a new type of cellulose acetate rayon in which the fibre is characterized by an inherent stabilized crimp, producing a yarn the behaviour of which is comparable in some respects to that of wool. One of the most important textile discoveries of recent times has been that of nylon. This is a truly synthetic yarn and is the first textile fibre prepared wholly of raw materials from the mineral kingdom. Although derived from coal, air and water, nylon can be produced in filaments of exceptional strength or as fine as a spider's web, yet having elasticity and lustre. Another striking development is to be found in the use of glass fibres. Objects showing this class of fibre include woven and knitted fabrics made entirely of pure glass with a collection of articles indicating the commercial applications. An exhibit of interest from Tokyo shows fibre and yarn produced from seaweed. Jute, sisal, and hemp are each represented, with examples of the latest types of yarns and materials produced from these fibres.

British Museum (Natural History): Acquisitions

RECENT acquisitions in the Department of Zoology include a collection of Northern Rhodesian mounted heads and skulls of ungulates made chiefly at Mpika by the late Mr. F. H. Melland and presented by Mrs. Melland. The collection contains some very fine sable and roan antelope heads and is of special interest in that the species represent a transition stage from the southerly types of South Africa to the more northerly forms found in Tanganyika Territory and Kenya Colony. Another interesting gift is the skull of a hippopotamus from Nigeria presented by Mrs. Piper. Purchases include a large collection of South American mammals from Dutch Guiana, and another from Ecuador. The latter is worthy of special mention since it contains a series representing that most interesting genus of Diprotodont marsupials, Caenolestes. The Department of Mineralogy has received a series of specimens of Darwin glass from Mt. Darwin, Tasmania, collected and arranged by the late Mr. Hartwell Conder and presented by his widow. Darwin glass is a silica glass. Thousands of tons of it in the form of rounded and rod-like pieces are found over an area of sixty square miles in Tasmania. It is believed that the silica-glass was formed by the heat engendered by the impact of a large meteorite. Some crystals of the rare mineral withamite, a pink variety of epidote, have been presented by Mr. W. G. Myers, who found them at the type locality in Glencoe where the new road has cut through the lavas in which withamite occurs. Good crystals of this mineral are rare. A very large rough crystal of microcline feldspar from Norway has been purchased. This crystal measures about 14 × 12 × 10 inches and weighs about 100 pounds.

Report on Abortion

THE report of the Inter-Departmental Committee on Abortion, which was appointed by the Minister of Health and the Home Secretary under the chairmanship of Mr. Norman Birkett, K.C., has been issued (H.M. Stationery Office. 2*s*. 6*d*. net). In the Majority Report, signed by fourteen members, the question of the prevalence of abortion is first examined. They stress the difficulties entailed in arriving at any estimate; but suggest that the number of abortions occurring annually in England and Wales is between 110,000 and 150,000, of which perhaps forty per cent are criminal. The Committee discusses the existing law, analyses the motives for criminal abortion and the methods employed, and examines proposals for amending the law. It recommends that the law should be clarified so as to make it plain that the induction of abortion is legal when the operation is carried out to save the life, or to prevent impairment of health, of the pregnant woman, but expresses strong opposition on ethical, social and medical grounds to any broad relaxation of the law. It is recommended that therapeutic abortions should be notifiable by the operator to the medical officer of health, and that there should be some restriction on the sale of abortifacient drugs. The majority of members of the Committee are not prepared on general grounds to recommend the unrestricted dissemination of birth control advice by the public health services.

The New Radcliffe Observatory

IN *Occasional Notes Roy. Astro. Soc.* (No. 4, March 1939), Dr. H. Knox-Shaw gives a very full description of the work on the erection of the 74-inch reflector at Pretoria, and three plates illustrate various parts of the equipment, the turret, the telescope itself as viewed from the north-east, and also the Newtonian observing carriage and the Coudé room. It is satisfactory to know that the pyrex disk for the large mirror has been successfully cast and the figuring will be completed in a few months, after which the mirror will be sent to Pasadena for aluminizing. It will be possible to use the telescope at three foci, Newtonian, Cassegrain and Coudé, the focal length in the first case being 30 feet, and the equivalent focal lengths in the last two being 111 ft. and 173 ft. respectively. The Newtonian focus will be used for direct photography and the other two for spectroscopic observation. A two-prism spectrograph for use at the Cassegrain focus is under construction and will soon be ready, and a projection measuring machine and also a microphotometer have been made for the Observatory. It is anticipated that the full programme of the work will be undertaken early in 1940, and the initial programme will include the determination of the radial velocities of the *O* and *B* type stars in the portion of the galaxy beyond the reach of the northern observatories. The object of this research is to corroborate present views on galactic rotation. When opportunities occur, photography of the nebulæ south of −40° declination will be undertaken

Museums and Children

THE revival of museum efforts which in Great Britain has followed upon the Miers report, has fortunately included in its sweep attempts to increase facilities for the interest and education of the young. But in this aspect of museum work America undoubtedly leads the way, and everyone interested in juvenile education must be grateful to Miss Ruth Weston for her impressions of American methods which appear as a supplement in the ***Museums Journal*** (39, 93, May 1939). Her first impression is one of the bold conception, enterprise, and general 'aliveness' which have produced such museums. Some are special children's museums housed in their own special buildings, in several instances right away from any other museum. Others form sections of larger museums, with special exhibition and other rooms for juveniles, either as an isolated wing or included within the main building. Sometimes the show galleries are supplemented by club rooms, library rooms, reading rooms, and a lecture theatre, which in Boston Children's Museum can seat more than 500. Loan collections of natural history objects for schools and even for individual child borrowers (as at Brooklyn), loan art collections, recording in colour and in black and white the development of art in different periods and countries (like the 2,000 reproductions at Toronto Art Gallery), have become the order of the day in these progressive museums. Much has been done in some British museums, but much more must be accomplished if museums are to play their part in the educational system; and there should be the less hesitation in transforming some of the now existing severe and aridly didactic galleries into simplified children's galleries, since our observation is that adults enjoy and benefit from the children's exhibits as much as the children themselves.

The World Power Conference

THE annual report of the World Power Conference for 1938, prepared by the Central Office of the World Power Conference, 36 Kingsway, London, W.C.2, has just been issued. There was a meeting of the International Executive Council in Vienna during August 29–September 1, attended by more than a thousand persons from thirty-seven different countries. The British Council was officially represented by Sir Harold Hartley and J. M. Kennedy. The British delegation numbered ninety-three and was nearly double the size of any other visiting delegation. Approximately two hundred papers were presented at the meeting. It is hoped to publish these papers and the discussions on them this year in the *Transactions of the World Power Conference*. A new national committee has been formed for Algeria, and there are now forty national committees. In response to an invitation issued and accepted in 1936, the second Chemical Engineering Congress of the World Power Conference will be held in Berlin in 1940. At the same time and place the third Congress on Large Dams will be held. The questions to be discussed have already been fixed. By invitation of the Swiss National Committee a meeting of the International Executive Committee will be held in Zurich shortly.

"Micro-entomology" at Stanford University

WE have received several parts of the journal entitled "Microentomology: Contributions to Entomology from the Natural History Museum of Stanford University". This periodical is now in its fourth volume, and it only publishes papers emanating from the Museum just named. The text is from manuscript expressly typed by the Stanford University Press and reproduced by the photolith method. This type of publication has been adopted as a partial solution of the prevailing high costs of printing by monotype and hand-set type. The reproduction has been admirably carried out, but the main factor in the process is the perfect typing of the copy, since the method affords little or no opportunity for errors and corrections. Among the papers published in this journal is a series of articles on the Coccidæ by G. F. Ferris and collaborators. These are well and clearly illustrated and, in fact, illustrations form the notable feature of this publication, the saving on printing costs allowing for an unusually large number.

New Seismological Observatory

IT is learned from *Earthquake Notes* (10, No. 4, April 1939), published by the Eastern Section of the Seismological Society of America, that a new seismological station is soon to be established at Bogotá, Colombia, South America. It will be at a height of some 2,800 m. above sea-level in the Northern Andes, and will thus be one of the highest in the world. This is made possible by a grant from the Carnegie Corporation of New York to the Jesuit Seismological Association, and the director of the station is J. Emilio Ramírez, S.J., of St. Louis University. The new station will fill a very noticeable gap in the map of seismological observatories, and will supply a definitely seismic area with important observational facilities.

The Lister Institute of Preventive Medicine

THE annual general meeting of the Lister Institute of Preventive Medicine was held on June 16 when the governing body presented the Institute's forty-fifth report. This contains a survey of the Institute's activities, with financial statement and the staff changes, during 1938, and a summary of the research work pursued. Studies on viruses are prominent, and Dr. Eagles has investigated a possible virus factor in the causation of acute rheumatism. Serological investigations include further work by Dr. Felix on the antigenic structure of the typhoid bacillus and on the standardization of therapeutic anti-typhoid serum, and a study by Dr. Muriel Robertson on the immune reactions *in vitro* of certain ciliate Protozoa. The nutritional value of buckwheat and its sensitizing action to light has been studied by Dr. Chick, and the results suggest that the nutritive value of the proteins of wheat are inferior to those of buckwheat. The National Collection of Type Cultures of Micro-organisms is housed at the Institute, and during the year some 6,300 cultures have been distributed, and many new strains deposited for maintenance.

National Baby Week

THE National Baby Week Council (117 Piccadilly, London, W.1) announces that 'National Baby Week' will be celebrated during July 1–7. Propaganda this year will be concentrated on "Fathercraft in the Child Welfare Movement", and the "William Hardt" challenge shield is offered for competition among senior girls in public elementary schools studying infant care. Full particulars may be obtained from the Secretary.

International Exhibition of the Art of Greater India

THE ROYAL ACADEMY, in collaboration with a number of connoisseurs of Indian art, is arranging to hold in January–March, 1940, an International Exhibition of the Art of the Indian Empire, French Indo-China, Netherlands, India, Burma, Malaya, Siam, Afghanistan, Tibet and Nepal. It is believed that the museums and private collections of those European powers most closely connected with the regions of Indian influence can furnish an exhibition of surprising interest and value, which would serve as a prelude to an exhibition of Indian art, drawn mainly from collections in Asia, to be considered when more settled conditions give a reasonable

NATURE

SUPPLEMENT

Vol. 144 SATURDAY, JULY 1, 1939 No. 3635

HISTORY IN THE ARCHIVES OF THE ROYAL SOCIETY*

By Sir William Bragg, O.M., K.B.E., Pres.R.S.

THE archives of the Royal Society are rich in materials that illustrate various aspects of the history of the last three centuries. They have, of course, a special character, since they refer almost entirely to the matters in which the Society has concerned itself, grouped under the general title of "The Improvement of Natural Knowledge". But these matters have increased in importance with the passing years and are now a subject of the first concern of the whole world. The effect of science upon social relations and social conditions has become very great, and the gains are obvious. Yet science does not appear to be in all cases beneficent. It has become a matter of anxious consideration whether or no the increase in the knowledge of Nature must necessarily bring evil as well as good. Is there a fault to be remedied, and if so, where does the fault lie? These questions have roused a debate which is even now in progress, and some hard thinking is being given to them.

It is of some help, I think, to consider the steps by which the present position has been reached, and the Royal Society archives may be used to provide the necessary illustrations.

A few 'virtuosi', to use the contemporary phrase, who met for discussion and experiment in the middle years of the seventeenth century, were weary of the miseries of the civil war, and were glad to turn their thoughts to the consideration of natural phenomena over which the passions of men had no influence. Experimental science had long tempted thoughtful minds, and now the first founders of the Royal Society threw themselves with thankful relief into a work which seemed to them to be both a pressing duty and an absorbing occupation. They were like boys let out of school rushing out into the surrounding world to explore brooks and hedges and anything that seemed interesting. When I take down the first volumes of the *Transactions* from the shelves or look through the early manuscripts at the Royal Society, I feel as if I was turning out schoolboys' pockets and finding the usual assortment of mixed oddities.

Early Activities

In its first efforts, the Society was mainly concerned with the collection of information. The leading fellows sent questionnaires to various parts of the world which in their demand for comprehensive detail would have done credit to any inquisitive department of a modern Government. An admirable example is to be found in the series of questions drawn up by Lord Brouncker and Mr. Boyle and approved at one of the earliest meetings of the Society; in which most appropriate suggestions were made as to what should be looked for on an ascent of Teneriffe. It shows no little knowledge and penetration to inquire whether a "filtre or siphon" would work as well at the top of the mountain as at sea-level, whether a bell or watch or gun would give the same sound, a flame have the same appearance, whether a pendulum clock went at the same rate, whether birds of heavy flight would fly as well or better or worse, and so forth. It was quite apt to ask what alterations would be found in living creatures carried to the top, both before and after feeding, and "what the experimenters do find in themselves as to difficulty of breathing, faintness of spirits, inclination to vomit, giddiness, etc."

On March 28, 1672, Lord Henry Howard presented the answers to a series of questions on

---

* From the second Pilgrim Trust Lecture, delivered before the U.S. National Academy of Sciences on April 24.

R 274

Barbary, where a retainer of his had recently been travelling: a remarkably pictorial account of the country and its inhabitants. It was expected apparently that some traces of the arts and sciences were to be found there, no doubt because it was known that the Arabian races had handed on the knowledge of the Old World to the New. But there was no learning at all. In particular "there were no chemists except Jews and Christian slaves that distilled brandy in jars". So, too, a good account is given of Hudson's Bay and its people by a Captain Guilliaume and a Mr. Bailes, who had recently voyaged there. Naturally most of the information relates to navigation and trade, but it is interesting to find also an account of the 'Maneto' or supreme power and of his priest the 'Pawaw'. The early records contain many such questionnaires and replies thereto.

Robert Boyle was the centre of a vast correspondence on scientific and other matters, and fortunately a large collection of his papers is possessed by the Society. Many or these have been published in his well-known "Life and Works". Quite a number of them crossed the Atlantic, and you will not blame me if I choose some of them to illustrate what I have to say. They were in the main of the informative type on which such great value was set. Thus a certain 'P.S.' writes from Virginia on August 29, 1688, describing humming birds, wampum, roanoke and pook, the latter being forms of currency. The trade measurement of length was the primitive cubit. The climate of New England was a frequent topic; it was supposed to be changing for the better. Perhaps under improving conditions the settlers were less susceptible to its rigours.

The governor of Boston, Leverett, and the deputy governor, Symonds, with other of their fellow citizens, write to Boyle in protest against charges of disloyalty to the King, anxiously rebutting accusations of neglecting the baptism of infants and so forth. In 1682, Hezekiah Usher begs the remittance for twenty-one years of the King's claim for one fifth of all minerals recovered, so that prospecting may be encouraged.

Boyle's correspondence was, as the last two extracts show, by no means confined to scientific matters. After all, the first founders of the Society were either statesmen themselves or closely connected with statesmen, and might well be supposed to be proper persons to be entrusted with important news. Thus Richard Wharton writes from Boston, warning Boyle that the French are working round the interior of the settlements towards Carolina and the South. In 1684, Randolph writes from New England of the possibility of drawing on the vast forests of Maine for supplies of masts and timbers for the navy, and discusses methods of making pitch and resin which are a secret of the French. John Winthrop writes in the same strain urging the Royal Society to approach the Government on the matter: he explains that there are sawmills handy to rivers, houses and provisions for workmen who may be sent, that small ships up to 400 tons have already been built. The supply of timber for the Navy was one of the greatest anxieties of Great Britain, from the time of this correspondence until steel replaced wood. Dry rot was a terrible curse from which the navy suffered more than the merchantmen, because the latter were more often aired and open to inspection during loading and unloading. A strange story of its ravages has recently been told by Ramsbottom in the *Essex Naturalist* (vol. 25). Among the incidents is the probable failure of the *Speedwell* to accompany the *Mayflower* on account of dry rot.

It is well known that Boyle was deeply interested in the conversion of the Indians and that the Society for the Propagation of the Gospel owes much to his initiative. In 1664 he receives a letter from John Endicott, of Boston, describing the progress of the mission. John Eliot, also of Boston, writes frequently, expressing deep gratitude, and hopes for further help. His address to Boyle was always eloquent, as for example "To the Right Honourable Learned abundantly charitable and constantly noursing Father".

In modern times it is an honour and an honour only to be elected a correspondent of a learned society. But a correspondent of the Royal Society in its early days was expected to correspond. When Cotton Mather was advised that he had been elected a fellow, he wrote in 1715 to his friend Richard Waller, the Society's secretary—the letter is in the Society's archives—saying that

> ". . . the tendency [of the Society] to Refine and Sweeten the minds of men, and reconcile them unto Just Regards for True Merits in one another, with an extirpation of that noxious clamour the party spirit, and finally how generously the more polite Literators of the world go on in it, with a decent contempt on the Banters of the Bruitish among the people, but the result of his consideration will be that it will be a greater honour to be taken into the list of your servants, than to be mixed with the great men of Achaia.
>
> "One who is entirely of that opinion, having been so listed with you has been desirous to discharge his obligations by agreeable assiduities, and therefore besides what every year brings you from him as an addition of Curiosities to the rich and vast assessment you are preparing he has bestowed a few hours upon the Philosophical Religion which he now humbly tenders to your acceptance."

The "Curiosities" here referred to became a famous object of interest in London; the collection was known as the "Repository". It grew to so great a size that the Society found it unmanageable, and handed it in 1782 to the British Museum, which had been founded a few years before in order, in the first place, to contain the collections bequeathed to the nation by Sir Hans Sloane. Sir Hans was president of the Society from 1727 until 1741.

The "Banters of the Bruitish" must clearly refer to the scornful comments of many clever men who did not sympathize with the experimental study of the world, who resented the intrusion of the new knowledge and laughed at the apparent futility and irrelevance of its beginnings. If they did not foresee the magnitude of its consequences, they were little more at fault than the experimenters themselves. How could intelligent men waste time on objects so small that they must be examined under the microscope ? Or on the consideration of such intangible substances as the air ? How could they give serious attention to the abnormalities and monstrosities that idle correspondents thrust upon them ? Of course, the Society did at first give its time to many accounts that even then must have looked ridiculous to men of a serious and settled mind. There were, for example, reports of a calf that had its hair inside out, of a man who squinted only on alternate days, of another who could not see if his hair were suffered to grow more than an inch long. It must have been quaint hearing when Dr. Tyson, at a meeting of the Society, declared that one of his teeth having been drawn at Oxford some years before had been replaced and had apparently taken root again, since it was still of use. In those early days of inquiry it was of course necessary to sift all information that came to hand, but it would certainly be difficult for the unscientific mind to see the point in all cases.

APPLICATION OF RESEARCH

These oddities were, however, an insignificant part of the Society's proceedings. Of far more importance among the Society's early papers are such as deal with the pressing questions of the day. Navigation claimed much attention. I have already referred to the anxieties respecting a sufficient supply of masts for the navy. Perhaps the Dutch and French were aware of those difficulties when, as Ramsbottom remarks, they were accustomed to fire high in a sea fight.

At the end of the seventeenth century, ships were growing considerably in size, since now they must become accustomed to the crossing of the Atlantic. Many English ports were unable to provide water of sufficient depth at all states of the tide, and tide tables were urgently required. Their calculation required the co-operation of mathematicians and astronomers. The archives contain of course many communications relating to the foundation of the Royal Observatory at Greenwich.

Pepys, when he was president of the Society, begged continually for information on any matter whatever that might assist him in his care for the navy. Probably he was really disappointed when Sir William Petty's double-bottomed ship turned out so badly, though he had made his bet that it would. Petty, a very able man, had supposed that a ship resembling in form two ships lashed side by side would stand up to a cross-wind better than a ship of ordinary design. The idea was that, of course, which is embodied in the outrigger of some Polynesian races. Again, there is an interesting note in the account of the *Proceedings* of July 28, 1686.

> ". . . it was remarked that sheathing with lead was the best expedient [for preserving ships from the worms] and found to be so by the experience of Sir Anthony Deane ; but that the carpenters finding it against their profit opposed it by affirming that the iron of the pintles of the rudders of ships so sheathed were much more apt to be corroded by the sea water than those sheathed with wood which yet was a groundless supposition."

The carpenters had more reason than was supposed ; we know now that electrolysis can be exceedingly troublesome.

So also the ventilation of coal mines was an urgent question, and is frequently referred to in the archives. It had become necessary to dig deeper than before. The accumulation of water became a serious hindrance and the many noxious damps were often fatal. Air pumps and water pumps are dealt with in numerous well-known papers by Boyle, Hooke, Papin and others. Sir Robert Moray wrote on the ventilation of mines in Belgium. There was much correspondence on the subject. Its general character may be illustrated by an extract from a letter which a certain Dr. Jessop of Yorkshire wrote to the Society in 1675. Let me give it in its original form, which now sounds so quaint.

> "There are four sorts (of damp) common in these parts. The first is *Ordinary Sort* of which I need not say much being known everywhere : the external signs of its approach are the candles burning orbicular and the flames lessening by degrees until it quite extinguish ; the internal, shortness of breath. I never heard of any great inconvenience which anyone suffered by it, who escaped swooning. Those that swoon away and escape an absolute suffocation are at their first recovery tormented with violent Convulsions, the pain whereof when they begin to

recover their senses, causeth them to roar exceedingly. The ordinary remedy is to dig a hole in the earth and lay them on their bellies with their mouths in it: if that fail they tun them full of good Ale: but if that fail they conclude them desperate."

These few extracts from the records of the Society will serve, I hope, to convey an impression of the character of the Society's activity in its early days, when first an organized attempt to collect knowledge by experiment and observation began to exercise its influence. At whatever point one picks up the story as it is told in these old records, one finds it full of interest, which lies not only in the subjects that are dealt with, but also in their relation to the activities of the time, and to the men themselves whose handwriting lies before one.

It is to be observed that these records are easily read by an educated man. Those who wrote them had in general no thoughts which the educated man could not follow, nor was it necessary to use terms which were not in ordinary use. Newton's "Principia" would, of course, be intelligible to a small number only, but in general the 'virtuosi' spoke a common language. The days of specialization and division into separate societies had not begun. How great is the contrast with the publications of a modern learned society!

It is also to be observed that there is no strict reckoning of services rendered, and no calculated recompense. Men like Hooke and other immediate servants of the Society were paid for their work, as was necessary and right, though the amount was incommensurate with their deserts. But the labours of the enthusiastic fellows and of their correspondents in all parts of the world were given freely. Indeed the Society had no money to pay with. It received no financial assistance from the Government, and the fellows' subscriptions (which, by the way, the treasurer found it remarkably difficult to collect) covered only the necessary expenses of the meetings. When the Society decided to print the "Principia", Dr. Halley himself provided the necessary funds. To this day, the fellows give without reward the services which their connexion with the Society entails. But I do not ask for any special commendation; the point is that such free service is common among learned societies, and is certainly a chief reason why they are held in respect.

The general intelligibility of the communications to the Royal Society persists for a long time. The calculations of the astronomers, the mathematicians, opticians and so forth appealed naturally to a limited number, but still we may suppose that fellows were able to understand the most part of that to which they listened. Perhaps it may be said, broadly, that the change begins when new terms must be invented to describe the increasing complexity of observations, and new units for quantitative description. Electricity and magnetism have been chiefly responsible; so that the experiments on frictional electricity which were so popular in the middle of the eighteenth century are especial objects of interest.

The progress of the subject is illustrated in the Society's archives by the many papers and letters of Watson, Franklin and others. Franklin's communications came by way of his friend Collinson, who gave them to Watson for presentation to the Society. Watson was himself a keen student of frictional electricity; and it would seem that some of the important experiments were made by Franklin and himself independently. But Franklin was, of course, the greater man, and Watson gave him full praise: "Although there are in the work some few opinions in which I cannot perfectly agree with him I think scarce anybody is better acquainted with the subject of electricity than himself."

Franklin was advised by his friend Mitchell that the paper on the subject of the identity of the lightning flash with the sparks of the electrical machine was received with laughter by the Royal Society. But the records in the *Journal Book* and elsewhere seem incongruous with such an occurrence. The warmth of Watson's praise, though he was an independent worker, his recommendation that Franklin's papers should be accepted, the repetition of Watson's commendation by the president when awarding Franklin the Copley Medal all go to show that there was probably no more than a hesitation to accept Franklin's view of the particular paper to which Mitchell referred; and the absence of some papers from the *Transactions* may well have been due to an arrangement with Collinson, who regarded the communications which he had received as private letters. At that time the *Transactions* of the Royal Society were not printed by the Society itself, but privately and independently.

The many papers in the archives that refer to frictional electricity form in themselves an interesting collection, showing the keen interest felt in the phenomena by experimenters in Europe and America, and they give additional strength, if it were needed, to Franklin's great reputation.

ACTIVITIES IN THE EIGHTEENTH CENTURY

Electricity was already, in the middle of the eighteenth century, offering a new field of experimental inquiry, and the importance of it was becoming realized. In the words of Martin Folkes, president from 1741 until 1752:

"Electricity seems to promise an inexhaustible Fund for Inquiry: and sure *Phenomena* so various and so wonderful can arise only from Causes very general and extensive, and such as must have been designed by the Almighty AUTHOR OF NATURE for the Production of very great Effects, and such as are of great Moment to the System of the Universe."

The numerous papers on frictional electricity form one of the most interesting sections of the archives during the eighteenth century.

The Society's membership did not equal in brilliance that of the centuries that preceded or followed. But there were several great subjects of consideration besides that in which Franklin made so prominent a figure. A large collection of Fahrenheit papers shows the interest taken in thermometers in the earlier part of the century. Another large collection deals with inoculation against smallpox. At the end of the century, Rumford describes his beautiful and valuable experiments on heat: he is prolix of words, but he makes excellent reading. He was, of course, a pioneer in the experimental study of the nature of heat. His work is well illustrated in the Society records. At the turn of the century the chemical investigations of Humphry Davy introduced a brilliant period in British science, and these also are well recorded.

The first quarter of the nineteenth century was not, however, a happy time for the Society. Internal dissensions and unchecked growth of membership, and the formation of societies which intended to take over special sections of the Society's work, until then unrestricted, all tended to reduce the value of the records and their interest. There were denunciations of the management and laments over the decline of science. Yet one of the greatest periods of scientific discovery had already begun, with Young, Fresnel, Davy and Faraday. But now the language began to be more difficult to the uninitiated. When the phenomena of electricity, magnetism, chemistry, light came to be studied in their mutual relations, the new world in which they figured was difficult of entry. This was not only because ideas were new and could only be represented with the aid of analogies, such as current, pole, capacity and the like, but also because new terms had to be invented to provide labels for conceptions which had never entered men's minds before. What, for example, could such words as anode and cathode mean to the non-electrician? So the ordinary reader is left behind, and the language of science becomes rapidly specialized.

It is interesting to observe the care with which Faraday chose his terms. He was in the habit of consulting Whewell, the master of Trinity College, Cambridge; the correspondence is preserved in Trinity College Library and in the Royal Institution. A letter in the possession of the Royal Institution reads as follows (Whewell is replying to Faraday):

"... I still think *anode* and *cathode* the best terms beyond comparison for the two electrodes. The terms which you mention in your last shew that you are come to the conviction that the essential thing is to express a *difference* and nothing more. This conviction is nearly correct, but I think one may say that it is very desirable in this case to express an *opposition*, a contrariety, as well as a difference. The terms you suggest are objectionable in not doing this. They are also objectionable it appears to me, in putting forward too ostentatiously the arbitrary nature of the difference. To talk of Alphode and Betode would give some persons the idea that you thought it absurd to pursue the philosophy of the difference of the two results, and at any rate would be thought affected by some. Voltode and Galvanode labour no less under the disadvantage of being not only entirely, but ostentatiously arbitrary, with two additional disadvantages; first that it will be very difficult for anybody to recollect which is which; and next that I think you are not quite secure that further investigations may not point out some historical incongruity in this reference to Volta and Galvani. ...

"I am afraid of urging the claims of *anion* and *cation* though I should certainly take them if it were my business—that which *goes to* the *anode* and that which goes to the *cathode* appearing to me to be exactly what you want to say. To talk of the two as *ions* would sound a little harsh at first: it would soon be got over."

The selection of the terms anode and cathode were based on a suggestion made by Faraday. In order to obtain a description which he could remember, he supposed his electrolytic trough to be placed parallel to the equator, and the current in the trough to run in the direction in which a current would have to run round the earth in order to give to the earth its observed magnetism. This implied that the current ran from east to west. It came, therefore, from the sunrise and went to the sunset, and the terms anode and cathode were taken as describing the way of the sun in the morning and in the evening.

Many groups of papers in the archives relate to work done for the Government, or for national enterprise, eclipse expeditions, biological and geodetic expeditions and so on. There is an interesting bundle of Sabine papers which have not yet been published. Sabine (1788–1883) was largely responsible for magnetic surveys in various parts of the world. Not a little of it is concerned with New England. There are letters from G. P. Bond, of Cambridge, the astronomical observer of the American Academy of Arts and Sciences, discussing the magnetization of the earth; from

I. M. Gillin, of the Observatory at Washington; T. D. Graham, of Baltimore; A. D. Bache, belonging to the Coast Survey, and so on. A letter from the secretary of the American Academy announces the appropriation (April 22, 1840) of 1,000 dollars for the purchase of instruments recommended by the Royal Society.

I shall say nothing of records more recent. We are all familiar with the bold advance of modern science, and extracts from the archives relating thereto would be superfluous. Specialization continuously increases. Papers become ever more complicated, each appealing only to a fraction of the scientific world and not at all to the general reader. The change from early times is very great indeed. It is inevitable and it implies success in experiment and deduction. But its effects are serious and must be examined carefully.

SCIENCE AND SOCIETY

These extracts show, I think, that the archives furnish a rich commentary on the history of the period during which the Royal Society has been in existence. They show, too, that the Society has played no small part in the doings which that history records. The new spirit which gave rise to the Society demanded that action should be based upon experimental research, and however spasmodically the world as a whole has obeyed this new principle, however ignorant men of all kinds, rulers and ruled, have been of the working of the leaven, the change in the ordering of men's activities has proceeded steadily and strongly. It has grown as the roots grow underground, preparing the life of the plant when the time comes for it to flourish. That time is already here, if we may judge by the extent to which natural knowledge is now used in all that men do.

We now observe the flower and the fruit that it bears. As we all know, we have reason both for satisfaction and for anxiety. We do see the happy results of a better acquaintance with Nature in a greater freedom from disease, in a richer life, in new opportunities for the exercise of talent, in a wider outlook. On the other hand, the problem of the well-being of the community is still far from complete. Not long ago the American Association for the Advancement of Science met in Richmond, Virginia, to hear a noble address from its president. The very title of his address, "Intuition, Reason and Faith in Science", was an indication of the position from which many of our most thoughtful scientists regard the problem as it stands to-day. From our side of the water we were glad to send Sir Richard Gregory to show that we also are trying to take our bearings for a new advance. We cannot stand still, of course; we must go forward, even though the way is not clear. We know the strength of science, we see that it has done great things, and are confident that its powers can be employed with greater and greater success as we give our whole minds to the problem that we have to solve. How shall we ensure the right use of natural knowledge, give full play to its beneficence and prevent its abuse? You and we and, let us hope, all associations of scientific men the world over, are of one mind in this matter, and are glad of the strength that unity brings.

The very fact that we share this goodwill points to the road that we must take. The goodwill that is based on our mutual understanding of what we are striving for is somehow to cover the world. I have not of course the presumption to say that science is by itself to leaven the whole. There are other incentives to co-operation; first and foremost stand the binding forces of pure religion. But the co-operation of the scientific workers is a new leaven, though it is not the first in the field. It is our own contribution which, if we can make, we must make or we fail in our duty to the world. I assume that we accept the duty.

We can surely conclude, from what we learn in the accumulated accounts of their doings, that the learned societies have not been unmindful of this primary purpose. No doubt in the early days when men collected facts as matters of interest, the recitals to which they listened were to many of them a private benefit only. Yet there were always men of wider vision who saw also the future benefit to their country or the world in the ordering of natural knowledge. The archives of the Royal Society, into which I have dipped here and there in order to provide illustrations of my argument, show the continuous endeavour of a body of men of science to be of help to their fellowmen. They may not have been always conscious of such an effort; in any community you may find some who are purely selfish. But as a body of men, vivified by those who had in them most of the right spirit, they have played a great part and I believe firmly a beneficent one

We cannot but ask ourselves whether it is possible to say that such and such actions and dispositions of societies like yours and ours have been the dispensers of good, while others are to be set on the opposite side. Some results derived from science are good: some already are bad. Are these antitheses related to similar opposites in our work as scientists?

Most thinkers now agree that we are not responsible for the uses that are made of the knowledge we find. We cannot control the strong passions that seize upon discoveries for selfish purposes. The work of discovery goes on and no one can stop it, not even ourselves. The constant demand for knowledge that is required for the solution of problems in health, in industry, in every human activity is so insistent that knowledge increases continuously and rapidly; and even if there were not this practical urge, there would be the never-failing curiosity to know more. We must therefore accept the position; we all seek for an understanding of how to make the best of it.

Exposition of Scientific Research

I have referred already to the addresses given recently by Dr. Birkhoff and Sir Richard Gregory. They illustrate a movement which gathers strength. It is based on an anxious determination to find out how the new situation is to be gauged and treated, and in particular, what the scientist may do. There is so much inquiry to be made before an answer can be given to this general question that it would be wrong to anticipate a conclusion. We can only remind ourselves of a few obvious lines of action, which we take in the expectation that the less obvious will become clear.

There is the great question of right exposition. It may be that there are some who would even now disclaim any duty of scientific men in this respect; and certainly there were many who would have done so in the past. If, however, we suppose that natural knowledge and the power which it gives are a common possession of mankind, we ought to make sure that what is found is understood. We cannot compel men to make use of science in the right way, but the chance that good use will be made is in a curious way dependent on the ease with which it is stated. If its expression is in forbidding terms, the man who sees no direct benefit from the effort of facing a difficult understanding leaves it alone. On the other hand, the man who is engaged in a fight against his fellows, whether in business or in war, grasps at any advantage that knowledge gives him, if he becomes aware of it; and of late years such men have seen the advantage, whence comes much of our present perplexity. The world is horrified by the development of frightful engines of war. It observes, too, that a technical invention, based it may be on some new scientific discovery, may throw great industries out of gear and bring misery upon employers and employed. These are obvious evils, and it is not surprising that the proper desire to increase knowledge is supposed to be associated with a tendency, even a desire, to make ill use of that knowledge. Also those men of goodwill who are acquainted with scientific aims and achievements have their own peculiar distress, because they know how little is done for the general good, compared to what could be done.

Exposition, therefore, becomes one of our chief concerns. It must be mated necessarily with the understanding that appropriate education can provide. We desire that all men, and especially men of goodwill, and especially also men of good education who are the natural leaders, should be aware of what science is doing and can do. A certain surviving distrust based on past misapprehensions has to be cleared away and replaced by co-operation.

I was standing once on the platform of a little up-country railway station in Australia, with others who had come to share the mild excitement of the arrival of the infrequent train. There was bustle when the train was ready to start, flag-waving, bell-ringing and cries to stand back. The engine whistled loudly—and went off by itself: the coupling with the train had been forgotten. There was a moment's pause, and then a shout of laughter while the shame-faced officials set out to repair their mistake.

There is something like that in what is taking place to-day. Scientific workers are so preoccupied with their business of research—naturally so—and in their researches have gone so far, that the world has no clear knowledge of the positions that have been reached. We have to see to the coupling and take the world with us. It may seem ungracious to make a statement of this kind when so much is already being done to popularize scientific knowledge. Yet it is to be observed that much of the science which is absorbed by the people lies on planes of lower value. Some that is intended for popular enlightenment is of that kind which seeks to dazzle by the recital of huge numbers. We must, of course, learn how narrow is our knowledge if we limit it to the consideration of spaces of about the same magnitude as our own bodies, or of times comparable with our own length of days. But that is a lesson in humility; the mere staring at big figures is childish if there is nothing more.

There are scientific writings which tend to be mystical and need very careful reading, lest they seem to contain a meaning when in fact they do not. Some of the terms used to describe scientific observations are drawn from the general vocabulary, such as wave, vibration, ray, ether and so forth, and are defined or re-defined for the specific purpose. If they are allowed to carry at the same time any unrestricted meaning that can be given to them in ordinary usage, an argument which includes them gets out of control and leads to danger.

The Spirit of Research

The observations of natural science, though they have now passed far beyond the range of the unaided senses, have not left the plane in which eyes and ears are accustomed guides. Neither they themselves not any combination of them rise to a higher plane; that is reserved for conduct, which, however, must take account of them.

The understanding of science that should be general to all men is of a simpler kind. It rests on a knowledge of the elementary laws of Nature, so far as we can ascertain them, and an appreciation of their continuous influence upon our lives. It leads to an awareness of the general position, though not necessarily a detailed acquaintance with it. It couples us all together in the desire to learn from Nature. We enrich our own lives, and we learn how to enrich the lives of our neighbours; but the great happiness lies in the discovery that there is a world in which we can all work together for the common good, in which there is endless work to be done, and an unselfish purpose can lead us from strength to strength.

Herein lies the finest work of science. Even the relief from pain and disability, the increase both in quality and in quantity of the fruits of the earth, the betterment of all the conditions of life, are not the end; there is something higher. It is the mutual service that is rendered when these things are fought for, and the happiness of mutual trust and reliance, and the last great act of virtue, that is to say, the sacrifice of self. To quote from Dr. Birkhoff's address: "I would state a fundamental truth about the social level which in some sense is the highest level of all [ranking, that is to say, above four other levels which he described, mathematical, physical, biological, psychological]: the transcendent importance of love and goodwill in all human relationships is shown by their mighty beneficent effect upon the individual and upon society."

Collectively and individually, men of science have done great things. Yet their achievements have value of one kind, and the spirit in which they worked has value of another kind; and the latter value is far more to be desired than the former. We may truly say of some of our greatest men of science that the world has gained more from their lives than from their discoveries, and this is so even if their influence on the world is limited to that which the world has been able to perceive. Their discoveries made them famous, but they themselves are better known than their discoveries. Faraday's reverence for truth and unselfish devotion to its acquisition have a higher value than the laws which he established. We gladly admit our debt to Pasteur and to the Curies, and yet the inspiration which we draw from their lives is even better than the results of their work. The world admires Franklin for his discoveries in electricity, yet it respects him more for his wisdom. I might prolong the list, but everyone can do that for himself. In brief, the spirit in which knowledge is sought and the manner in which it is used are more important, more real, than knowledge itself.

The records of scientific discovery, of the development of the fields of experiment which began three hundred years ago, have shown the growing power of science. The extent of their power is to-day a chief concern; we must, as so many are now trying to do, give anxious thought to its exercise. The power is not actually in the hands of the scientist, though he is deeply interested in its future because he has been, and is, the occasion of its existence. It may fairly be inferred from experience that the scientist himself will never be a tyrant. His work does not rouse in him the desire to dominate, but rather to assist. Love of accuracy, patience, perseverance, self-denial have been common qualities and necessarily so. These have a place in the general esteem, and therefore have their effect. Most of all the world respects the devotion to service that has so often been found; the warm love of their fellows which has inspired so many to give themselves and their labour without counting the return. We must hope that such a spirit will continue in ourselves, whether as individuals or as societies.

The problems of society, and in particular those into which natural knowledge enters so powerfully, will long demand a patient examination. But whatever may be the tactics that are developed in the end, it is certain that the satisfactory solution will be based upon moral influence. It is for us, as scientific workers, to supply the natural knowledge and help in its application; but that is not the complete account of what we have to do. Our effectiveness will depend, as is shown by all human history, including our own limited experience, upon the devotion, wisdom and goodwill which we bring to our task.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST ALBANS

prospect of successful organization. The co-operation of the French Government has been secured, and that of the Dutch Government is expected. The executive committee of the Exhibition is under the chairmanship of Sir Edwin L. Lutyens, and Sir John Marshall and Sir Richard Winstedt are vice-chairmen. The assistance of experts in the great museums containing Indian collections has been promised.

The Night Sky in July

Astronomical twilight (the sun not greater than 18° below the horizon) lasts all night in the latitude of London until July 21. The moon is full on July 1 at 16·3h. and again on July 31 at 6·6h.; it is new on July 16 at 21h. Mars is in conjunction with the moon on July 3, Jupiter on July 9, Saturn on July 11, Mercury on July 18, and Mars again on July 30. Mercury is at greatest elongation (27° E.) on July 13, and may be visible in the evening twilight up to about July 10. Mars and Jupiter both rise in the late evening. Venus continues as a morning star, rising at 2h. 50m. in mid-July. On July 23 Mars is in opposition and near its greatest apparent brightness, −2·6m., which is brighter than Jupiter is at any time. At this opposition, the diameter of the disk of Mars subtends 24″. The least distance separating Mars from the earth on July 27 is just over 36 millions of miles. On July 17 between 4h. 12m. and 5h. 0m., Jupiter will appear without its four bright satellites. Satellites II, III and IV will disappear by being eclipsed by the parent body between 2h. and 3h., and Satellite I begins to transit the disk of the planet at 4h. 12m. At 5·0h., Satellite IV will re-appear from eclipse. The next occasion when a similar phenomenon will occur is on July 10, 1942. The ring system of Saturn is now well opened, the diameter of the minor axis of the outer ellipse of the outer ring being about 11″. Neptune, in the constellation Leo, makes a close approach on July 30 to the star B.D. + 4° 2492, magnitude 8·7; the minimum distance between planet and star will be about 20″. Amongst the meteor showers due with their maximum late in this month are the Sagittids and the δ Aquarids.

Announcements

The Council of the Institution of Civil Engineers has awarded a Charles Hawksley Prize of £150 for 1939 to Donald Henry May, of Clapton, London, for his design of a grain-silo. Arthur James Francis has been "honourably mentioned", and a grant of £50 has been awarded to him for his design of a steel highway bridge.

On the recent occasion of the 150th anniversary of Schiller's inaugural lecture at the University of Jena, the Society of Medicine and Natural History of Jena presented the anatomist, Prof. R. Spanner, with the bronze memorial medal in recognition of his outstanding work on anatomy, and especially his researches on arterio-venous anastomoses.

A committee has been formed to celebrate the quatercentenary of the death of Paracelsus; it is under the presidency of Prof. Laignel Lavastine of Paris, with the collaboration of Cornil, dean of the Marseilles medical faculty, Abel Rey of the Sorbonne, Garraux, president of the Swiss Medical Federation, Cawadias of London, Verzar, dean of the medical faculty of Basel, and Anderes, dean of the medical faculty of Zurich.

Applications for grants from the Permanent Science Fund of the American Academy of Arts and Sciences are invited for consideration by October 1, 1939. Applications should be made on special forms furnished by the Committee. Further information can be obtained from the chairman of the Committee on the Permanent Science Fund, Prof. John W. M. Bunker, Massachusetts Institute of Technology, Cambridge, Mass.

A studentship, established in memory of Edward Teshmaker Busk, who in 1914 lost his life while flying an experimental aeroplane, will be awarded in July. The studentship is of the value of about £150, tenable for one year from October 1; but a student may be re-appointed on the same terms for a second year. It is open to any man or woman being a British subject and of British descent who has not attained the age of twenty-five years on October 1. The object of the studentship is to enable the holder to engage in research, or preparation for research in aeronautics. Further information can be obtained from Prof. B. Melvill Jones, Engineering Laboratory, Cambridge.

The Twelfth International Congress of Psychology will be held in Edinburgh during July 22–27, 1940. Further information can be obtained from Prof. Godfrey Thomson, Moray House, Edinburgh 8.

In September of this year—most probably during the second fortnight of the month—Messrs. Carl Zeiss, Jena, will hold the fourth technical-scientific course of lectures on spectrum analysis, photometry, microscopy and fine measuring. During the principal lectures, new results of practical value concerning modern material-testing and fine measuring will be dealt with. Sufficient time will be reserved in the form of informal discussion for purely scientific research, and short lectures will also be delivered. This year ample opportunity will be provided for practical work with the instruments under the guidance of experts. Further information can be obtained from Messrs. Carl Zeiss, Dept. ZWA, Jena, Germany.

A first supplement, covering the years 1935–36, has been issued to the catalogue of foreign books in the Tokyo Imperial University library. The catalogue is arranged in ten sections covering general and miscellaneous; philosophy, religion, education; languages, literature, fine arts; history, biography, geography; law and politics; economics, commerce, public finance, statistics, social sciences; science; engineering, industries, army and navy; medicine and agriculture. Each section consists of an author index and an alphabetical list of periodicals.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 37.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Instability of the Mesotron and the Gravitational Constant

THE recent discovery that the mesotron is unstable in free space introduces into physics a new dimensional constant, the mean life τ_0 of a mesotron at rest, of magnitude about $2\cdot5 \times 10^{-6}$ sec. It is convenient to consider not τ_0 but the related fundamental length $L_0 \equiv c\tau_0 \doteqdot 7\cdot5 \times 10^4$ cm. This length is very much longer than any of the lengths, ranging from 10^{-14} cm. to 10^{-8} cm., which can be formed out of the constants e, $\hbar$, c and the various fundamental atomic masses. Thus, without using large powers of the non-dimensional atomic ratios (for example, $\hbar c/e^2 \doteqdot 137$), it is not possible to express L_0 in terms of these constants alone.

If L_0 is to be related to the other natural constants, it is clearly necessary to include the gravitational constant G. When this is done, the following expression gives at once the right order of magnitude:

$$L_0 \sim R_0 \frac{e}{w}, \tag{1}$$

where $R_0 \equiv e^2/\mu c^2$ and is the 'classical' radius of a mesotron of mass μ, and $w \equiv \mu G^{1/2}$ is its 'gravitational charge'. The use of w instead of G is advantageous, since it brings the gravitational forces $G\mu^2/r^2$ into the same form as the electrostatic forces e^2/r^2.

Since $\mu \doteqdot 170\, m$, where m is the mass of an electron, $R_0 \doteqdot 1\cdot6 \times 10^{-15}$ cm., and, since for a mesotron $e/w \doteqdot 1\cdot2 \times 10^{19}$, the right-hand side of (1) gives 2×10^4 cm., in rough agreement with the observed value of L_0. Another possible form of (1) is, of course, $(r_0/137)\,(e/w)$, where r_0 is the 'classical' radius of an electron.

It would be attractive to conclude from this result that perhaps the decay of the mesotron may provide a link between atomic and gravitational phenomena. This implies, on Yukawa's theory, that there must also be a connexion between gravitation and β-decay.

Nothing so far has been said of the neutrino, into which, together with an electron, a mesotron is supposed to decay. If a neutrino has a finite rest mass μ_0, this might have been brought into the calculation, and if the mass were of the right magnitude, there would be no necessity to introduce G. For example, if $\mu_0/m \sim 10^{-15}$, L_0 can be expressed simply as $L_0 \sim \hbar/\mu_0 c$. In view of (1), we have $\hbar/\mu_0 c \sim R_0 e/w$, and this would be interpreted as showing that the mass of the neutrino, as well as the life-time of the mesotron, is connected with gravitation.

There is one possibility that would make all this argument false. It is the unlikely one that perhaps the life-time τ_0 of the mesotron, as measured in the earth's atmosphere, may not be the same as that in free space, but may depend on the local conditions, for example, on the local gravitational, electric or magnetic potentials.

Reaction between Hydrogen and Oxygen Sensitized by Nitrogen Peroxide

NITROGEN peroxide exerts a powerful catalytic effect on the combustion of hydrogen[1]; small quantities may depress the ignition temperature by so much as 200° C. (for example, addition of 0·09 mm. NO_2 lowered the ignition temperature of 100 mm. H_2 + 50 mm. O_2 in a porcelain vessel from 580° to 370° C.). At any particular temperature the sensitized ignition is confined between readily reproducible, narrow limits of concentration of nitrogen peroxide outside which a slow catalysed reaction occurs. It was further shown[2], in this laboratory, that a simple correlation exists between the induction period found to precede the onset of both the slow reaction and the ignition, and the catalytic effect of the nitrogen peroxide on the slow reaction and the ignition. The results were interpreted by assigning to nitrogen peroxide the dual role of stimulation of chain branching, and inhibition by the direct termination of chains. This stimulation of branching may be visualized if we suppose that the nitrogen peroxide, by participation in a collision with some highly energized link of the chain, is dissociated and gives rise to an oxygen atom.

The fact that induction periods precede the slow reaction as well as the ignition, and that the plot of induction period against concentration of nitrogen peroxide shows no discontinuity as the ignition points are passed, shows that even in the region of slow reaction the system possesses a positive 'net branching factor φ'. This positive value of φ leads to an exponential increase of the number of centres with time, and at the end of the induction period, when their number increases very rapidly, these become increasingly subject to removal by recombination in three-body collisions, a process which depends on the square of the concentration of centres. Through the interplay of branching and self-neutralization, the number of centres and hence the reaction rate, thus tend to potential equilibrium values. It was concluded[2] that ignition only occurs when some critical volume element becomes self-heating; a condition which intervenes when the potential equilibrium concentration of centres reaches a critical value.

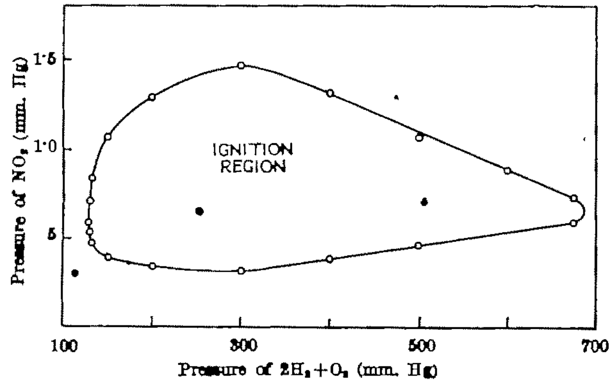
Additional evidence for this point of view is now provided by the study of the effect of pressure of reactants and foreign gases on the induction period and ignition limits.

(*a*) *Foreign gases.* Addition of foreign gas to an explodable mixture of hydrogen, oxygen and nitrogen peroxide of constant composition, progressively lengthens the induction period and eventually converts the ignition into a slow reaction. For four foreign gases the relative amounts necessary to quench ignition are:

$$A : N_2 : He : CO_2 : : 6 : 3{\cdot}6 : 3 : 1.$$

The order of effectiveness in lengthening the induction periods is the reverse of this. These results are explained if the foreign gas can alter the net branching factor φ by deactivation of energized chain centres, which would otherwise lead to branching by collision with nitrogen peroxide molecules. Further analysis of the results indicates that, in the case of helium, the high thermal conductivity may also enter as a major factor determining the ignition condition.

(*b*) *Pressure of reactants.* At a given temperature, increase in the pressure of reactants causes the upper limit to rise to a maximum and then to fall; whilst the lower limit, though less dependent on pressure, falls to a minimum and then rises. The accompanying diagram shows the effect of pressure on the limits in a pyrex vessel of internal diameter 7·0 mm. at 364° C. This result is readily interpreted on the thermal theory. The fact that increase of pressure progressively shortens the induction periods to an almost constant low value, indicates that the explodability of the mixture as measured by the net branching factor progressively increases to an almost constant value. To this cause must be attributed the initial widening of the explosion region. At higher pressures, however, the increased probability of recombination of centres in three-body collisions decreases the equilibrium reaction rate and causes the explosion region to shrink.



A more complete account of these and related experiments, together with a quantitative development of the theory, will be published elsewhere.

Reflection of Medium and Short Radio Waves in the Troposphere

THE discovery that radio waves could be reflected in the troposphere was announced by us[1] and immediately corroborated by Watson Watt and his coworkers[2]. Since that time, many observations have been made upon both long and short waves and the diffraction theory of G. N. Watson[3] has been simplified for numerical calculation. The calculations show that diffraction alone will not account for the intensity of the received signal. It was then thought by some experimenters that refraction due to changing air densities might be responsible for most of the bending in the troposphere. However, Englund and his associates[4] have clearly shown that the waves (in their case less than 5 metres in length) are reflected from the boundaries of different air masses.

We have been examining the tropospheric reflections of medium and short waves (1,614–17,310 kc.) at vertical incidence for almost four years, and our observations are in complete agreement with Englund's theory for short waves. For example, whenever a cold high-pressure area comes in from the northwest, the measured height of the *C* region falls, rising again as the high is succeeded by a low-pressure area from the same direction.

In order more fully to confirm our theory that the medium and short waves could be reflected vertically from the interface between two different air masses, we have sent up an aeroplane which took readings on the air temperatures at different heights directly over the radio station, while we were measuring the heights of the reflecting layers by means of the radio pulse. Several flights have been made with the following results:

Flight	Date	Height of *C* region by radio pulse above sea-level (km.)	Height of temperature inversion by aeroplane above sea-level (km.)
1	Dec. 22, 1938	1·4	1·2
2	Dec. 28, 1938	1·09	1·04
3	Jan. 2, 1939	1·2 1·8 } two reflections	1·15 1·7 } two reflections
4	Jan. 5, 1939	1·52–1·9	1·5 turbulent air
5	Jan. 6, 1939	1·14–1·29 1·50–1·63 } two reflections	1·16 discontinuity 1·56 sharp inversion
6	April 22, 1939	1·45–1·75 2·3–2·6 } two reflections	1·4–1·65 2·1 } turbulent air

This is the first direct comparison between the two methods. The agreement is nearly perfect. The aeroplane was furnished by Dr. L. S. Adams, president of the Tri-State Aviation Corporation.

Using two transmitting sites simultaneously, we have measured the same reflection heights over various base-lines in different directions. Frequencies between 1,614 kc./sec. and 17,310 kc./sec. failed to show any marked differences in the heights of the reflecting regions. The strength of the reflected waves decreased at the higher frequencies. During the past three years, all the stronger reflections have come from regions between 0·5 km. and 2·5 km. above our altitude of 0·29 km.

Potentials at Oil-Water Interfaces

WHEN a water-immiscible phase, called an oil, separates two aqueous phases, there is in general a potential difference between the aqueous phases. Since this potential difference is much greater than those found when electrolytes diffuse freely in water, it has been assumed that diffusion in the oil cannot account for the observed potentials[1]. Bauer[2] at one time, and more recently Ehrensvard and Sillén[3], suggested that these potential differences are caused by adsorption at the interfaces. Craxford, Gatty and Rothschild[4] pointed out that adsorption as such can only influence potential under two conditions, namely, if the interface is a perfect insulator or if adsorption influences the rate of diffusion of ions across the interface. Unless the interfacial monolayers have a resistance to anions or cations comparable with the bulk phases, it can be shown that they cannot affect the potential when a steady state has been attained.

I have measured the potential difference between a hanging drop and a sessile drop of water in oils lighter than water in such a way that the thickness of the oil between the interfaces could be varied. Albumin attached to a moist glass fibre can be passed through the oil and spread at either interface. When both interfaces are protected by albumin films, they can be pressed together so that only a thin 'soap bubble' of oil remains between.

There is a quick change of potential when albumin is spread at an oil-water interface, so that the water becomes negative with respect to the oil. This potential difference decays to zero at a rate that increases with increasing conductivity of the oil. With oils of specific resistance of 10^9 ohms, the half-life is about 10 minutes, at 10^5 ohms only a few seconds. Sweeping with a brass barrier in the usual way produces similar time potential curves even if the interface is originally quite clean.

At the oil-water interface, the oil molecules can be regarded as forming an oriented monolayer with their polar groups in the water. As a consequence of this sheet of oriented dipoles, charge separation across the interface will build up diffuse double layers in both phases, so that at equilibrium there will be no potential difference across the system. If the diffuse double layer is disturbed, either by changing the dipole fields or by sweeping with a barrier, time will be required to re-establish equilibrium in the two phases. Since a spreading film drags with it quite thick layers of water[5], and presumably oil, the potentials observed after spreading a protein film may be due largely to mechanical disturbance of the double layer.

The addition of electrolytes to one of the aqueous phases will produce diffusion potentials if one of the ions is more soluble in the oil. Methylene blue chloride and sodium eosinate both produce high potentials of opposite sign as if the dye ions were diffusing into the oil ahead of the Cl^- or Na^+ ions. Using butyl acetate as the oil, eosin can be seen diffusing into the oil and the potential falls in a few hours. With high resistant oils these potentials fall more slowly, and methylene blue chloride in 0·01 molar potassium sulphate against octyl alcohol maintained a negative potential of more than 70 mv. for 24 hours. Protein films at the interface have no effect on these diffusion potentials. However, if two drops protected by protein films be pressed together, reducing the oil to a thin film, the potential drops to zero, since there is insufficient resistance in the thin oil phase to maintain a concentration gradient of appreciable magnitude in the oil. With octyl alcohol it is sometimes possible to separate the drops and regain the diffusion potential. With butyl acetate the films stick together to form a stable triple layer that prevents convection but has little or no effect on diffusion or potentials and has a resistance of less than 0·5 ohm cm^2.

The above considerations throw doubt on any explanations of steady bio-electric potentials based on interfacial potentials or diffusion potentials across thin oil films. However, since some monolayers can retard the evaporation of water, it is possible that monolayers may exist that can influence oil-water potentials by virtue of their low ionic permeability.

A full account of these experiments with further theoretical treatment will be published elsewhere.

Adjustment of Electrical Units

THE international body responsible for the allocation of values to electrical units, the General Conference of Weights and Measures, decided at its last meeting, in 1933, to change at some future date the long-accepted value of the ohm; no more regrettable decision could have been taken.

Recent measurements show that the ohm is 5 parts in 10,000 greater, and the ampere 1·5 parts in 10,000 less, than the values originally aimed at for them. As a result, the watt measured electrically is about 2 parts in 10,000 greater than the watt derived from the metre, kilogram and second. Physicists and electrical engineers agree almost unanimously that, for practical reasons, the electric standards ought to be adjusted so as to secure equality of the 'electrical' watt and the 'mechanical' watt.

But adjustment can be effected in several ways. The method contemplated by the General Conference of Weights and Measures is to reduce the volt by 3·5 parts in 10,000 and the ohm by 5 parts in 10,000. The change in the volt would cause no serious difficulty, but the change in the ohm entails re-engraving practically all resistance boxes, for all precision resistance boxes claim an accuracy superior to 5 parts in 100,000.

There is no doubt whatever that if an adjustment so large as 5 parts in 10,000 were made, the great standardizing laboratories, universities, scientific institutions, etc., would desire to possess standards in agreement with the new value of the ohm. The replacement of existing apparatus, much of which is all the more valuable for having been under observation for many years, would be extremely wasteful. It is also entirely unnecessary, for adjustment of the watt can be effected by keeping the ohm as it is at present, and reducing the ampere and the volt by 1 part in 10,000, as pointed out by G. Giorgi[1], G. A. Campbell[2] and others.

As the alteration of the ohm has not yet been enforced, it is to be hoped that the General Conference will not lack courage to examine, in the light of fresh facts and new arguments, a question in which there is a considerable body of opinion opposed to its earlier decision.

Acoustic Properties of Mud Bricks

FOLLOWING up our tests of the thermal properties of mud bricks[1], we have investigated their acoustic properties by reverberation methods for sound absorption, and by direct methods for sound insulation.

The sound insulation of a 9-inch mud brick wall (uncracked) is determined by the weight per sq. foot, as is known for many other materials. Cracking commenced as drying proceeded, accompanied by a marked fall in the sound insulation.

The sound absorption of an irregular mud brick surface is very considerably greater than the same wall finished with a smooth mud surface. The measurements explain the short times of reverberation in mud brick rooms.

The results are as follows :

Sound absorption (O.W.U.)			Sound insulation in decibels				
			Age of wall				
Frequency of sound	Irregular surface	Smooth surface	1 hr.	1 day	3 days	9 days	30 days
250	0·32	0·10	45·6	46·5	39·0	31	31
500	0·48	0·16	53·9	49·9	42·2	35	33
1000	0·56	0·19	64·4	55·8	50·5	40	40
2000	0·55	0·18	—	—	—	—	

The bricks were composed of 97·5 per cent mud and 2·5 per cent straw by weight.

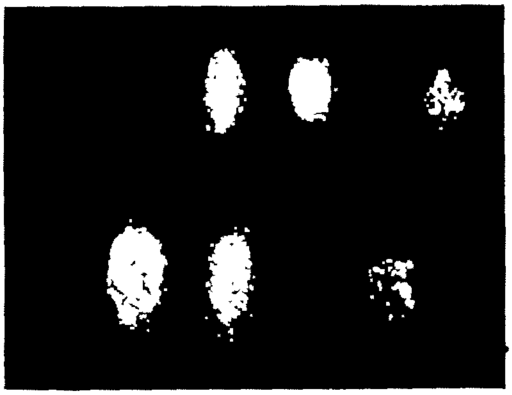
Spring Development of the Gonads of the Starling (*Sturnus v. vulgaris* L.)

IN 1937[1] and 1938[2] Rowan reported some interesting differences in the state of the gonads of the starling in winter. The gonads of birds obtained in London were considerably larger than those of birds obtained from flocks frequenting a roost in the country, and this was interpreted as indicating that the noise of traffic, by causing the birds to be restless throughout the night, had induced a precocious development of the reproductive systems. Bissonnette[3], however, failed to obtain this result experimentally.

It is known that the winter starling population of the British Isles is derived from two main sources. The results of bird marking have shown that the majority of British breeding birds remain in the country throughout the winter, whilst their numbers are greatly augmented in autumn by flocks of starlings coming from the Continental countries bordering the Baltic and the North Sea. These immigrants, which leave Britain again in March, congregate at night in roosts which contain tens of thousands of birds. It is possible, therefore, that the starlings taken by Rowan in London were British, whereas those taken in the country were Continental.

With this alternative explanation in mind, starlings were obtained between March 11 and March 21 from a quiet residential district two miles from the centre of Leeds. In this area the birds roost, for example, under the eaves of houses, where they are not subject to any disturbances from traffic during the night. No increase in their numbers can be noted during winter, and the extremely dirty condition of their feathers is additional evidence that they are town birds. These birds proved difficult to obtain, but, of the six examined, the three males were in full breeding condition. They had large white testes (see accompanying reproduction, No. 4) and their seminal vesicles contained spermatozoa. The ovaries of the females were small (No. 5), and afterwards it was found that this sex does not come into full breeding condition until the middle of April.



GONADS OF STARLINGS. NATURAL SIZE.

For comparison with these birds, which were almost certainly British, starlings were also obtained from a roost which had been established during the previous autumn in a small plantation near Beamsley Beacon in Wharfedale. Estimations, supported by photographic evidence, showed that about ten thousand birds occupied the roost each night, and it is probable that the great majority of these were of Continental origin. Between March 7 and March 14, thirty-one birds were obtained in the plantation, and, with one exception, these were sexually undeveloped. In the fifteen males, the testes (No. 1) were small and dark grey in colour, and microscopic examination showed that they were completely quiescent. The vasa deferentia and seminal vesicles were small and embedded in fat. In the females, the ovaries (No. 3) were slightly smaller than those of the town birds, and only minute eggs were present. The oviducts were very slender. These birds were therefore in a similar state to those obtained from the country by Rowan in February 1937.

One male bird, however, obtained in the roost on March 9, was entirely different. The testes (No. 2) were almost fully mature, each being large and white in appearance, and the seminal vesicles were correspondingly well developed. Although obtained in the open country, this bird was in the same condition as those in the Leeds suburb, and it therefore appeared possible that a number of local starlings were present among the thousands of immigrants occupying the roost. This was finally proved when all the Continental birds suddenly left on March 15. A small residual population of about a thousand starlings remained to roost in the plantation each night, and, at the time of writing (May 13), they are still continuing to do so. These birds were clearly local, and they were discovered to come from a small area of some five square miles immediately adjacent to the roost. Fifteen specimens were obtained between March 22 and 25, and the seven males proved to be uniformly similar to that one male bird obtained in the roost on March 9.

Although the separation of British and Continental starlings depends on circumstantial evidence, it nevertheless appears probable that a difference exists between the times of onset of sexual activity in these two types of birds. The onset of maturation in the starling is almost certainly conditioned by the increase of daily light in the early months of the year, and it would appear that these two types of birds possess different reactions to the same environmental changes. The British birds react early and do not migrate. The Continental birds react more slowly and migrate before reaching their full sexual development.

Morphologically, the two types of starling have not been separated, but, if these results are substantiated, it is apparent that they should be treated as distinct physiological races.

Formation and Breakdown of Glycogen in the Live

Parnas and Baranowski[1] have shown that glycogen undergoes a special kind of breakdown in muscle to hexosemonophosphate. The authors term this phosphorolysis of glycogen:

$$(C_6H_{10}O_5)_n + n.H_3PO_4 = n.C_6H_{11}O_5.PO_3H_2.$$

Ostern, Guthke and Terszakowec[2] identified the product formed under these conditions as a mixture of Robison and Neuberg esters.

Cori, Colorick and Cori[3] found that the intermediate step in the breakdown of glycogen to the Robison ester was the glucose-1-phosphoric ester described by them. They further showed that the glycogen phosphorylating enzyme is widely distributed and that in dialysed liver extracts it forms from glycogen glucose-1-phosphoric ester, which is partly dephosphorylated to glucose. It seems therefore possible to them ". . . that the blood sugar of mammals is produced by this enzyme system rather than by a diastase"[4].

We have used concentrated liver brei made by grinding 1 part of the liver of starved rabbits with 1 part of phosphate buffer solution at *p*H 7·2. Glycogen added to the brei is rapidly broken down as well in the presence as in the absence of fluoride. With fluoride, Cori ester is quantitatively formed, and then converted to Robison ester; provided that excess of glycogen is present, only so much is broken down as can be phosphorylated by the amount of phosphate available. Without fluoride, glucose is formed, no uptake of inorganic phosphate being detectable; this is because dephosphorylation is so rapid that the primary phosphorylation of glycogen is masked. It can, however, easily be demonstrated by the addition of $M/200$ fluoride, which completely inhibits the dephosphorylation. Under these conditions, the phosphorolysis proceeds in the liver at the same speed as in muscle; at a glycogen concentration of 2 per cent and at 37°, nearly 4 gm. of glycogen is phosphorylated by 100 gm. of liver in one hour. A velocity of breakdown of glycogen of this magnitude would be sufficient to maintain the blood sugar of an animal in face of its physiological requirements, even during exercise.

In the presence of oxygen, the phosphorylation and breakdown of glycogen are quicker than in its absence, probably because the reaction is accelerated by the oxidative removal of part of one of its products —the Robison ester.

Phlorrhizin inhibits the breakdown of glycogen in liver by more than 70 per cent. Since it specifically poisons the phosphorylation of glycogen[3], this is further proof that phosphorolysis is the chief, if not the only path of the anaerobic and aerobic glycogen metabolism in the liver.

Cori ester, added to normal liver brei, is rapidly dephosphorylated; in the presence of fluoride, most of it is converted to Robison ester, but a part of it forms a substance which gives an opalescent solution, is dextro-rotatory (α_D about +190°), gives a red-brown colour with iodine*, does not reduce, but is precipitable by alcohol, and reduces after hydrolysis. We think, therefore, that this substance is glycogen. In an experiment in which 80 mgm. of Cori ester was added to 10 gm. of liver brei poisoned by fluoride, 7·6 mgm. of glycogen was formed, corresponding to about 20 per cent of the Cori ester. The reaction is thus clearly similar to that described by Schaffner[5] and by Kiessling[6] as taking place in yeast. Since phosphorylations are involved in the formation and breakdown of glycogen in liver, it is understandable that glycogen from liver (however carefully prepared) contains some organic phosphorus[7].

* Cori, Schmidt and Cori reported recently (*Science*, 89, 464; 1939) that glycogen is formed from Cori ester by purified muscle enzymes. The fact that their product gives a blue colour with iodine is very interesting, and shows perhaps that there are differences between the synthesis of glycogen in liver and in muscle.

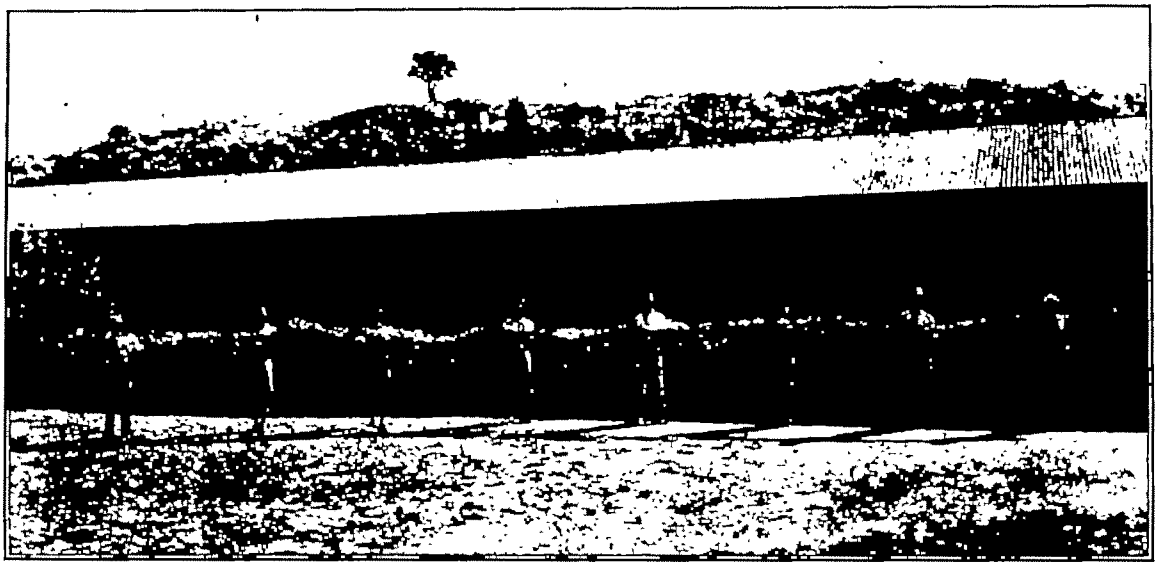
A Grass Leviathan from East Africa

DURING an expedition which the Government of the Union of South Africa sent recently to East and Central Africa for the purpose of collecting grasses which might prove of value to the Union for pasture, ay, silage and erosion control, a remarkable grass vas encountered and collected in East Africa and has ince been grown at the Department of Agriculture's rass Introduction Research Station at Pretoria with stonishing results. The grass combines all the ttributes of a pasture, hay and soil preserver in uch a remarkable manner that it is felt that it leserves more than ordinary notice. The grass elongs to what is known locally in East Africa as he Star grasses. These occur commonly in the Rift Valley and are regarded amongst the farming community, both black and white, as the best and most nutritious grasses in ranching country. For example, n the country around Lake Solai, the dry bed of which is covered with these grasses, it has long been the custom of stockowners who have grazed their animals in the country around Nakuru, where they invariably suffer from 'nakuritis', to send them o the rich Star grass pastures of Lake Solai, where they immediately pick up in condition and recover.

These Star grasses belong to the genus Cynodon Rich., to which the common dog's tooth, Bermuda grass, couch grass of Australia, Bahama grass of the West Indies, the doub grass of India and the kweekgras of South Africa also belong. There is great variation both in the habit and structure of these grasses, but they are usually placed by botanists under the name *Cynodon plectostachyum*.

A number of these Star grasses were encountered by the expedition in Tanganyika and Kenya, but on examining the grass plots laid down at Kabebe, near Nairobi, by Mr. D. C. Edwards, grassland officer to the Government of Kenya, I was shown a remarkable Star grass in one of his plots, which he stated had appeared there by accident and had evidently been introduced by seed contained in a sod of a fine-leaved lawn grass (also a Cynodon) from Uganda. Apart from this, the origin of the grass was unknown. This Star grass was standing nearly three feet high in the plot, and was regarded as a promising hay type. The edges of the plot, however, were kept closely trimmed and thus little indication of the true character of the grass was manifest. The grass was so outstanding that it was decided to keep a sharp look-out for it. The expedition first encountered this giant Star grass in its natural habitat in the evergreen and deciduous parkland country between Eldoret and Kitale in the Trans Nzoia province of Kenya, and along the eastern foothills of Mount Elgon. Afterwards it was collected frequently in Uganda in the neighbourhood of Ruwenzori, in the Semliki Valley, around Lake Edward and Lake George and in several localities in the eastern Belgian Congo.

Apart from its luscious and dense stand, often 3–4 feet in height, the most remarkable character of the plant in the veld was its amazing network of robust runners or stolons, and it was at once realized that in this plant Nature had provided us with valuable material for erosion control. Living material was brought to Pretoria and was planted out under conditions where the growth of the plants could be studied in detail. The plants have been under observation for some five and a half months and during this period, under a rainfall of 27·49 inches, they have made remarkable growth.



A GIANT STAR-GRASS RUNNER (WITH OFFSHOOTS) MEASURING 48½ FEET IN 5½ MONTHS FROM THE TIME THAT IT LEFT THE PARENT PLANT.

GROWN AT RIETONDALE PASTURE RESEARCH STATION, PRETORIA.

Individual plants during this time have covered more than eight thousand square feet of soil, and in many instances have put out runners (with offshoots) from the parent plant, measuring in length more than fifty feet. These runners and offshoots, of course, anchor themselves down firmly at almost every node. The material offers great possibilities for erosion control in areas where this grass can be successfully established.

Oxaloacetic Acid in the Leguminous Plants

INVESTIGATIONS in our laboratory have revealed that oxaloacetic acid has a central position in biological fixation of nitrogen. Recently P. W. Wilson[1] reported that, contrary to the findings in this laboratory, he has not been able to find oxaloacetic acid in the growing legumes. In the determination of oxaloacetic acid, Wilson employed the aniline manometric method of Ostern, making the determinations in the expressed sap of the plant material from which the proteins are precipitated with tungstate in a sulphuric acid solution.

Oxaloacetic acid disappears easily from the plant material during the preparation of the sap if the respiratory system is active. Therefore we have employed a different procedure in preparing the plant sap. Since oxaloacetic acid is most stable in alkaline solution—according to Straub the stability increases at least up to *p*H 14—we add caustic soda solution (1 c.c. of 10 per cent solution per 3 gm. fresh plant) and fine quartz sand to the plant material. The mass is rubbed fine in a mortar and the sap pressed through a cloth. Thus the sap is kept alkaline—*p*H about 12–13—right from the start and the respiratory system is destroyed. The sap is cooled at 0°, sulphuric acid is added to lower the *p*H to about 5, the solution is added to Ostern's buffer solution and the carbon dioxide formed through aniline is determined manometrically in the Warburg apparatus. By this method we have found, for example, in the leaves of young red clover grown in the greenhouse in April–May, 48–264 γ oxaloacetic acid per 1 gm. The accompanying table illustrates one of our determinations carried out with red clover at the start of flowering. Oxaloacetic acid was destroyed in one experiment by heating the acidified plant sap.

t° C	Minutes	Thermo-barometer	4 c.c. dil. plant sap + 2 c.c. buffer + 0·05 c.c. aniline + 0·2 c.c. water		4 c.c. dil. plant sap + 2 c.c buffer + 0·25 c.c. water. No aniline
			Exp. acc. to the method described	Sap acidified and heated	
8·9	0	151	153	149·5	151
9·3	30	167	179	165·5	167
		16·0	26·0	16·0	16·0
Change in the pressure			10	0	0
Oxaloacetic acid (γ) per 1 c.c. sap			104	0	0

Daily and diurnal variations are considerable, as would be expected. After flowering of peas, oxaloacetic acid is no longer found.

We have modified for plant material also the method of Szent-Gyorgyi and Straub for the colorimetric determination of oxaloacetic acid. Two samples of equal size are taken from the plant material. Hydrazine hydrochloride is added immediately to one sample and the mass is rubbed fine in a mortar. To the other sample is added sulphuric acid to make the *p*H of the mass about 3, and the mass is kept at room temperature for 4 hours to destroy the oxaloacetic acid completely. Both samples are then extracted with ether in a percolator for 36 hours. The ether solutions are shaken frequently with soda solution. The soda solutions obtained are acidified with sulphuric acid to *p*H 2–3, cooled at 0°, whereupon sodium nitrite solution is added. After 5 minutes, the solution is made strongly alkaline with caustic potash and the yellow colour formed thereby is determined colorimetrically. The difference in the colours of the two samples should be due to th amount of oxaloacetic acid. The reliability of thi method is being further investigated by us. On th basis of the determinations hitherto, the latte method seems to give higher values than the manometric method described above. If the plant material is made strongly alkaline right from the start, as described in connexion with the manometric method, the values obtained by the manometric and colorimetric methods have been in good agreement in the determinations hitherto carried out.

In the article referred to, Wilson states also that he has not been able to bring about nitrogen fixation with excised root nodules in the solution of oxaloacetic acid. This result is at great variance with the numerous experiments carried out in our laboratory. In most experiments we have determined the nitrogen fixation by Kjeldahl's method, and also in some experiments by determining the amount of nitrogen in the gas mixture[2]. In addition, we have noted the increase of amino nitrogen in the solution in the presence of oxaloacetic acid and the formation of oxime nitrogen. So far as we can see, there cannot be any doubt about nitrogen fixation with excised root nodules.

A more detailed account of our experiments will be given in the *Biochemical Journal*.

Discovery of Sugar-cane Seedlings

AN interesting review of the book "The World was my Garden", by David Fairchild, appeared in NATURE of December 31, 1938, p. 1138. In this review I note the following sentences: "There are occasional slips, as for example on p. 123, when the late Dr. J. B. Harrison is described as being the discoverer of sugar-cane seedlings. In Barbados and the West Indies generally, this honour has always been ascribed to the late John R. Bovell."

Neither the reviewer nor the author of the book is strictly correct. Seedling canes were found by the overseer of a Barbados plantation so early as 1858, and the discovery recorded in the Barbados *Liberal* of February 12, 1859, while the fertility of the cane was established at about the same time in Java, Reunion and Mauritius. Systematic research work on the production of new seedling varieties of sugar-cane dates from the re-discovery of the fertility of the cane by Soltwedel in Java in 1887. The discovery of seedling canes in Barbados by Harrison and Bovell, referred to by the reviewer, was a joint one made in 1888, and quite independently from that of Soltwedel. The six months period separating the dates of the Java and Barbados discoveries is explained by the fact that the cane produces its flowers in May–July south of the equator, and in November–January in the northern hemisphere. Bovell afterwards became renowned as the breeder of the world-famous *BH*.10(12) and several other valuable seedling cane varieties, while Harrison went to British Guiana and worked with cane seedling in that country.

Cotton Mycorrhiza

THE mycorrhizal habit among tropical crops is becoming more generally recognized. A few years ago when I was isolating Fusarium from cotton roots, I noticed in the cortex the presence of fungal hyphæ which were clearly differentiated from Fusarium mycelium. I also observed that certain sparsely septate hyphæ with very characteristic projections were always found in close proximity to cotton roots.

I did not pay much attention to these structures at the time because I was concentrating on Fusarium. However, during my recent work on cotton mycorrhiza, I found the typical vesicular-arbuscular endophyte within the cortical tissues. Penetration takes place through the piliferous layer. The hyphæ penetrate two or three layers of cells and then pass into the intercellular spaces of the cortex and sometimes penetrate into the cells themselves. Vesicles of an inter- or intra-cellular type are developed in certain strains of cotton. They are terminal, round, oval or irregular. The arbuscule sporangiole apparatus is found within the inner cortical cells next to the endodermis.

Butler[1], in his recent paper on the occurrences and systematic position of the vesicular-arbuscular type of mycorrhizal fungi, named the endophytes *Rhizophagus* sp. According to his statement, he found the endophyte scarce in Gujerat, whereas in the Sudan cotton the roots were transformed into mycorrhiza and the extra matrical development of the fungus was very luxuriant.

In conclusion, it may be said that *Rhizophagus* sp. appears to grow in the soil around the cotton roots and also within the cortical tissues, producing vesicles in the first case and vesicles and arbuscular sporangioles in the second. The factors which influence the presence of the endophyte within the roots are now under investigation; but from the results so far obtained it seems that soil type, manuring and the age of the plant are chiefly instrumental.

Points from Foregoing Letters

It is shown by P. M. S. Blackett that if the observed lifetime of a mesotron is to be related to the other fundamental constants, that the gravitational constant must be included. This can be done in a very simple way and may indicate a relation between atomic and gravitational phenomena.

R. G. W. Norrish and F. S. Dainton have studied the effect of pressure of reactants and foreign gases on the critical concentrations of nitrogen peroxide, and the induction periods of the hydrogen-oxygen reaction sensitized by nitrogen peroxide. The authors consider that the inhibiting effect of foreign gases is due in part to the deactivation of highly energized chain centres, and that at high pressures the inhibiting effect of reactants is due to the increased probability of self neutralization of centres.

Direct observations of temperature changes at various levels of the atmosphere by means of aeroplane flights, made simultaneously with radio measurements carried out directly underneath, to determine the height of the reflecting layers, are reported by R. C. Colwell and A. W. Friend. They confirm the view that medium and short waves can be reflected vertically from the interface between two air masses.

R. B. Dean states that oil-water potentials disappear when the oil is reduced to a very thin film, because the thin oil film is no longer able to maintain a diffusion gradient in itself. Potential differences set up when a protein is spread at one interface disappear in a short time owing to the formation across the interface of a neutralizing double layer in both phases.

P. Vigoureux suggests that the necessary adjustment in the value of the watt should be made by keeping the ohm as it is at present and reducing the ampere and the volt by 1 part in 10,000; this would obviate the scrapping of much valuable apparatus in many laboratories.

The sound absorption of an irregular mud brick surface is found by F. H. Constable and M. K. Mahas to be considerably greater than the same wall finished with a smooth surface, which accounts for the short time of reverberation in mud brick rooms.

A comparison of the gonads of British and Continental starlings points to a difference in the time of onset of sexual activity in these two forms. It is suggested by W. S. Bullough and R. Carrick that they may constitute separate physiological races.

P. Ostern and Eric Holmes state that the chief path of glycogen breakdown in the liver is by way of phosphorolysis to Cori ester, which is either dephosphorylated to glucose or converted to Robison ester. In fluoride poisoning, added glycogen is converted to Robison ester so long as phosphate is available for esterification. The excess of glycogen can be recovered, whereas without fluoride the whole of the glycogen disappears, owing to the circulation of phosphate, which is rapidly freed from hexose monophosphate. In the presence of fluoride, part of the added Cori ester is converted into glycogen and part into Robison ester.

A photograph of a giant Star-grass runner (*Cynodon plectostachyum*) from South Africa is submitted by I. B. Pole Evans. It grew 48¼ ft. in 5¼ months from the time it left the parent plant, and may prove to be a very valuable plant for erosion control.

A. I. Virtanen and A. A. Arhimo describe a method for the determination of oxaloacetic acid in plants. Considerable quantities of oxaloacetic acid are found in growing legumes at definite times of day. Daily and diurnal variations are great.

E. C. Stevenson writes that seedling canes were found by the overseer of a Barbados plantation so early as 1858 and the discovery recorded in the *Barbados Liberal* of February 12, 1859, but systematic research work on the production of new seedling varieties of sugar-cane dates from the re-discovery of the fertility of cane by Soltwedel in Java in 1887.

RESEARCH ITEMS

Rock Paintings and Engravings of the Western Sahara

THE first of a projected series of studies of the scientific results of Théodore Monod's expeditions to the Western Sahara in 1934–36 is devoted to rock-paintings, engravings and inscriptions (*Pub. du Com. d'Études Hist. et Scientifiques de l'Afrique Occidentale Française*, Sér. A, No. 7, 1938. Paris: Lib. Larose. Pp. 156 + 9 pls.). It includes an iconography, accompanied by a complete enumeration of known sites, followed by general remarks on classification and chronology, with a study of the inscriptions by Georges Marcy. The material of this western area is poor both in quantity and quality in comparison with the remarkable assemblages in southern Oran, Ajjers and Fezzan. Only Libyco-Berber graffiti are at all abundant, and that only in certain areas. The western material falls into two, or strictly speaking three, classes, as compared with the seven or eight distinguished by H. Winkler in the desert of Upper Egypt. The chronological problem accordingly is simplified. In the west is (I) a single undifferentiated neolithic. Next comes (II) a Libyco-Berber group, also homogeneous, but with local facies of unknown chronological relation. Thus the camel abundant at Tichitt-Oualata is rare at El Beyyed, while at Chinguetti it is the horse that predominates. Groups I and II can be distinguished readily. They belong to different cultures, of which I alone is prehistoric. Differences of patination are evidently a result of local conditions, and the only sure guides to classification are technique, style and content. Hence a 'bovine' period, corresponding, it may be assumed, to a sedentary agricultural neolithic stage, which at times was ichthyophagous, is followed by an equine-camel period, in which the lakes of the last humid phase gradually disappear and climatic conditions would appear to deteriorate. Even an approximate dating cannot be suggested, as there is no fixed point for the close of the neolithic and the arrival of the Libyan horsemen, while the only *terminus ad quem* is the Islamization of the country.

Respiratory Metabolism of Infant Brain

H. E. Himwich, Z. Baker and J. E. Fazekas (*Amer. J. Physiol.*, 125, 601; 1939) studied the respiratory metabolism of the brain of infant rats (1–24 days old) with the following results. (1) Like the adult brain, the infant brain is dependent on added carbohydrate (glucose) for maximum respiration and possesses a small aerobic glycolysis. The respiration of the infant brain is also stimulated by lactate, succinate, pyruvate and fructose. (2) On the basis of *dry* weight, during the first eleven neonatal days the rate of glucose oxidation is lower than that of lactate. In the absence of substrate and the presence of lactic acid the respiration is the same as that in the adult. (3) The oxygen consumption of the brain of the new-born rat is smaller than that of the adult brain per unit of *wet* weight of tissue. (4) The diminished capacity for oxidation may be correlated with the protein concentration, which is lower in the infant brain. The authors therefore suggest that the diminished oxidation is a quantitative rather than a qualitative phenomenon.

Human-Birth Weights

H. P. DONALD (*Proc. Roy. Soc. Edin.*, 59, 91–108; 1939) has analysed the factors influencing the birth-weight of 3,000 infants at the Else Inglis Memorial Hospital, Edinburgh. The average weight tends to be higher in the summer than in winter. Sex, order of birth, age of mother, and family characteristics are shown to influence the birth-weight. The view is favoured that birth-weight is more a quality of the mother than of the children.

Inheritance of Cataract

A RECESSIVE gene in the rat causes the degeneration of the retina of the eye about seventeen days after birth. M. C. Bourne and H. Grüneberg (*J. Hered.*, 30, 131–136; 1939) have examined histologically animals homozygous for this recessive gene. They find that in all cases the rod nuclei die and lesions appear. Secondary effects may or may not be present, such as persistence of the hyaloid artery and degrees of opacity of the lens (cataract). The characteristics resemble retinitis pigmentosa, an inherited anomaly in man. This case is interesting in showing one constant effect of a gene combined with several inconstant characteristics.

Heterochromatic Regions of Chromosomes

IN many recent cytological publications there has been an increasing tendency to recognize deeper affinity for stains in certain regions of the chromosomes. These regions more retentive of stains are described as heterochromatic. Dontcho Kostoff (*Proc. Ind. Acad. Sci.*, 8, Sect. B; 1938) has collated various aspects of this question; he points out that the regions near the centromeres tend to be heterochromatic and may persist in interphase as prochromosomes, whilst the end regions may also be heterochromatic, and sex chromosomes are often markedly so. After platinum chloride fixation and gentian violet staining, Kostoff concludes from his preparations that the chromomeres are more closely spaced in the heterochromatic regions, and this leads to his support of Koltzoff's suggestion that genes are possibly located between the chromomeres. The paper also puts together an interesting series of phenomena, such as the effects of infection by micro-organisms, glandular secretions and X-ray effects, and discusses their possible influence on chromosome conjugation and 'somatic' crossing-over. The paper has evidently lost much in its expression in the English language, but the ideas suggested, with the bibliography, are well worth consideration.

Lepidoptera of the Mascarene Islands

A CATALOGUE of these insects from the above-mentioned islands, by J. Vinson, has lately (December 1938) been published by the Mauritius Institute and Public Museum (*Mauritius Inst. Bull.*, 1, Part 4). By the expression 'Mascarene Islands' the author includes the islands of Réunion (Bourbon), Mauritius and Rodriguez. This definition is now very generally used in entomological writings. The catalogue enumerates 387 species and, of these, 43 per cent r 168 species are endemic but only 14, or 6 per cent, f the genera are actually endemic. On the whole, he fauna of Lepidoptera is considerably richer in he Mascarenes than in the Seychelles. While there re certain cosmopolitan elements in the fauna such s the butterfly *Vanessa cardui* and such moths as *Heliothis armigera, Ephestia cautella, Pyralis farinalis* nd *Plutella maculipennis*, there are others of more pecial interest. Thus *Papilio phorbantia* is confined o Réunion and *P. manlius* is only found in Mauritius. here are also Danaid butterflies of the genus Euploea, amely, *E. goudotii, euphon* and *desjardinsi*. They are onfined to Réunion, Mauritius and Rodriguez espectively. Among the moths, the sub-family Hypeninæ provides many peculiar and restricted pecies. For example, of the twelve species of Hypena, even are endemic in Mauritius or in Réunion. The mall moth *Crambus seychellus*, which is unknown utside the Seychelles, is represented in Mauritius nd Réunion by a distinct race, namely, *emmerezellus*. ts larva is a serious pest of lawns in Mauritius where t has become known locally as the lawn cut-worm. Mention needs also to be made of the family Metaphandidæ the species of which are almost all confined o the Mascarenes and Seychelles, with a few species n India.

Life in Arctic Ice and Snow

A report recently issued by the Smithsonian Institution gives an account of E. Kol's studies of plants growing in ice and snow in the Mount McKinley National Park, Alaska. Reference is made particuarly to three organisms, and the remarkable feature which emerges is the prolific growth that occurs during the short season when the surface of the ice or snow melts temporarily in the August sun. The surface of the Columbia Glacier is described as covered for miles by light brownish-purple algal vegetation known as ice-bloom; the organism responsible is the green alga Ancyclonema, which Dr. Kol has also found in various localities in Europe, but never in sufficient quantity to form ice-bloom. Above Valdez, around the Thompson Pass, the snowfields at the beginning of August showed the phenomenon of red snow, the coloration extending from the surface to a depth of several inches, and in one case to two feet, into the snow. The effect is produced by *Chlamydomonas nivalis*. The red snow in this particular pass looked as if sprinkled with red pepper, instead of the raspberry red of some other snowfields. In snowfields of the mountain above Juneau, masses of tiny snow fleas were present, piled to a depth of about half an inch and giving the surface a deep violet-grey colour.

Vegetation of the Aka Hills, Assam

N. L. Bor has recently published a synecological study of this area (*Ind. For. Rec.*, New Ser., Botany, 1, No. 4, Govt. of India Press, New Delhi, Nov. 1938). Hitherto, the area from a botanical point of view was practically unexplored, for nothing but a meagre collection, by Griffith, in the foothills was known of its flora. The area was of importance phytogeographically because it lies midway in the four hundred miles wide gap between Sikkim and the Arbor Hills, areas, especially the former, well known botanically. A preliminary survey of the area is given, the biotic factors are outlined, and the various vegetational units are grouped into climax and seral communities. The special relations existing between vegetation and water in quantity are discussed in a chapter headed "Hydroseral Communities". Some important chapters are devoted to economic factors. Dr. Bor was able to collect some 3,500 species in all, though he does not pretend to have been able to visit the whole area. As an indication of the interest of the paper, the discovery of *Quercus incana*, Roxb. within this tract bridges the enormous gap which has hitherto existed between its known habitats in the north-west Himalaya and Upper Burma; whilst *Juglans regia*, L., and *Populus ciliata*, Wall, so common in the north-west Himalaya, are now found to extend well into the eastern Himalaya. A last example of a 'find' is *Salvia japonica*, Thbg. var. *parviflora*, not previously recorded outside its Chinese home.

Fungal Lodging of Wheat

The 'lodging' of wheat and other cereals has been ascribed to various causes such as excess nitrogen or wet weather, but Mary D. Glynne of Rothamsted Experimental Station has shown (*Agric. Progress*, 16, Pt. 1, 1939) that the fungus *Cercosporella herpotrichoides* is frequently responsible for the weakening of straw at harvest time. The organism attacks young wheat plants in late autumn or early spring, and produces dark-coloured lesions upon the leaf-sheaths and leaves. It spreads through the summer, until the lumen of the straw is often filled with light grey mycelium. There is much evidence that nitrogenous fertilizers and wet conditions increase the incidence of the disease, so that control by the avoidance of these conditions is still valid. The widespread distribution of mycological lodging makes it possible, however, to adopt further measures, such as long rotations to starve the fungus, and the wide separation of wheat and barley within the rotation.

Micro-Manipulative Studies of Virus-infected Plants

Miss F. M. L. Sheffield, of the Rothamsted Experimental Station, has adopted a fascinating technique for the investigation of virus-infected cells of *Solanum nodiflorum, Hyoscyamus niger* and other plants (*Proc. Roy. Soc.*, B, 126, 529–538, February 1939). Micromanipulative puncture of the cell, by the methods of Péterfi, followed by a suitable test, has shown that the relative acidity of both virus-infected and healthy cells of *S. nodiflorum* and *H. niger* is approximately the same, namely, pH 6·8. Non-crystalline intracellular inclusions of aucuba mosaic disease in tomato disintegrate immediately with slight mechanical pressure, or on pricking. The inclusion breaks down in 0·07*M*. concentrations of sodium, potassium or calcium chlorides, but can be removed in 0·1*M*. solutions of these salts. Infection experiments with such removed material have demonstrated that the inclusions contain virus. Striate material of tobacco mosaic and enation mosaic cannot be isolated, as it breaks down into needle-like fibres when touched.

An Electromechanical Transducer

The electromechanical transducer in the new Benioff seismograph is the subject of a paper by James J. Delvin, S.J. (*Bull. Seis. Soc. Amer.*, 28, No. 4, Oct. 1938). The original transducer was possessed of hysteresis difficulties and itself rendered the motion of the seismograph unbalanced. E. C. Bullard also questioned the validity of the shunt in the magnetic circuit and suggested a balanced transducer. The new transducer, it is suggested by the author, overcomes all these difficulties. A diagram of the pole pieces, armature piece and air gaps is given, and this is followed by a mathematical analysis of the working. It is found that the E.M.F. output, E, is governed by the equation

$$E = k\frac{\varphi_m}{x_0}\frac{dx}{dt},$$

where k is the number of turns in the coil, φ_m is the flux through the permanent magnet, x_0 is the length of the air gap in the central position of the transducer, and dx/dt is the rate of change of the air gap. In the new instrument the variations in flux are more nearly linear, the symmetry of the design renders unnecessary any calculations for the lack of symmetry such as the added stiffness of the spring in the vertical component, and there is now no such thing as an unbalanced horizontal component.

Seismological Data from the Far East

VALUABLE data of seismology are contained in publications of the Government of India Meteorological Department, and the Royal Observatory, Hong Kong. The former, contained in the *Seismological Bulletin* for April–June 1938, contains interpretations of seismograms for the Observatories of Agra, Bombay, Calcutta, Colombo, Dehra Dun, Hyderabad and Kodaikanal, together with non-instrumental reports. At Agra, 20 shocks were registered in April, 32 in May and 11 in June, commensurate numbers being registered at the other observatories. In the *Hong Kong Bulletin* of March 1939, detailed interpretations are given for 26 shocks registered there, together with all instrumental constants. This brings the total of shocks registered at Hong Kong during 1939, up to the end of March, to 74.

Crystal Structure of Glycine

ALTHOUGH there have been detailed studies of many proteins, less attention has been given to the simpler amino acids which are the basis of the more complicated structures. The crystal structure of glycine has been the subject of three investigations, which are in poor agreement. G. Albrecht and R. B. Corey (*J. Amer. Chem. Soc.*, 61, 1087; 1939) have now made an X-ray examination of the structure of glycine in which the Patterson-Harker analysis has been used. A full account of the parameters is given and the results indicate that the structure consists of nearly flat glycine molecules held together by hydrogen bonds between adjacent nitrogen and oxygen atoms to form continuous layers throughout the crystal. Interatomic distances in the molecule are: carbon-oxygen 1·25 and 1·27 A., carbon-carbon 1·52 A., carbon-nitrogen 1·39 A., each with a probable error of ±0·02 A. Hydrogen bond distances between nitrogen and oxygen in the same layer are 2·76 and 2·88 A., and between neighbouring layers 2·93 and 3·05 A. A discussion of the probable distances of hydrogen atoms leads to the conclusion that the atomic arrangement is a *zwitter*-ion structure for the glycine molecule in the crystal.

The Electron-Microscope and the Investigation of Viruses

THREE important articles on the use of the electron microscope have recently appeared in *Die Naturwissenschaften* (27, 281–299; 1939). The first, by von Borries and E. Ruska, deals with the nature of the image obtained by the use of the electron ultramicroscope, in which the object is traversed by a beam of electrons. The second article, by H. Ruska, deals with the technique of work with the instrument, and particularly with the preparation of the object to be observed. The various types of carrier for the object, corresponding to the glass slide in ordinary microscopy, are considered. The carrier must be perfectly transparent to a beam of electrons, and must be uniform in thickness, and free from irregularities which would be visible under the electron microscope. A collodion film is satisfactory, and the methods of preparing the specimen on the film for observation are dealt with. A process for increasing the sharpness of an image lacking in contrast is also described. The most interesting of the three articles is the final one, by Kausche, Pfankuch, and H. Ruska, which gives the results of the investigation of plant viruses with the electron ultramicroscope. Recent progress made in the determination of the size and shape of the tobacco mosaic virus molecule is reviewed. By drying the virus solution on the carrier film, a dry gel with a definite structure is obtained. By using a sufficiently diluted solution (10^{-8} gm. of virus protein per c.c.) the lateral aggregation of the particles to bands can be prevented, so that the rods and threads can be dried out isolated from each other. The dimensions of the particles can be obtained. They vary in length, but are usually multiples of 300 mμ long, though some are multiples of 150 mμ. The diameter is about 15 mμ, or multiples of this. It is considered that the virus molecule is 300 or 150 mμ long, by 15 mμ in diameter, other dimensions being due to aggregation. Infection is brought about by one particle. If the particles are broken down by chemical means, they cease to be active.

Determination of Stellar Diameters by Interferometer

Reinhold Fürth, Kurt Sitte, and Hans Peter Appel (*Mon. Not. Roy. Astro. Soc.*, 99, 3; January 1939) have described a modification of the Michelson interferometer method for the determination of stellar diameters. The Michelson interferometer method for finding stellar diameters is not applicable unless the air perturbations are very small. In most cases these are so great that the image of the star in the telescope moves quickly and it is impossible to see its interference fringes. If a diffraction grating is used to produce fringes and the grating is translated in its plane, the fringes do not move, and this principle has been used in the apparatus described in the paper. A secondary image of the primary interference image is produced by a suitable optical arrangement, and when the primary image is moving because of the air perturbations, the secondary image remains at rest. When the primary Michelson system of fringes disappears at a suitable distance of the slits, no secondary interferences are formed. In addition, when the contrast of the primary interferences has its maximum, the secondary will show at its optimal visibility. For these reasons the secondary interferences can be used instead of the primary to determine stellar diameters. Photographs of secondary fringes in still and disturbed air, produced by an artificial star with a diameter 0·32 mm., show that air perturbations have practically no effect upon the clearness of the interferences figures. The laboratory experiments show that stellar diameters can be measured even when there are strong air perturbations, and it is claimed that an accuracy of 10–15 per cent can be attained.

EXCAVATIONS AT AMARAH WEST, SUDAN, 1938-39

AN exhibition of antiquities, the results of an excavation carried out at Amarah West in the Sudan on behalf of the Egypt Exploration Society, was opened in the Department of Archæology and Egyptology of University College, in the University of London (Gower Street, London, W.C.1), on June 20, and will remain open until July 15 daily from 11 a.m. to 5.30 p.m.

AMARAH WEST: REMAINS OF AN ANCIENT TREE, ONE OF A SERIES, WHICH FLANKED THE ENTRANCE TO THE TEMPLE

The ancient fortified site of Amarah West in the Northern Province of the Sudan is situated between the second and third cataracts of the Nile, about 120 miles south of Wadi Halfa. It is on the left bank of the river, and consists of a small walled town overlooking the river, and cemeteries and other ancient remains in a wide circle round the town. The town crowns a small mound, and is so deeply buried by sand and other debris that before excavation no walls were visible. Originally a brick enclosure between 100 and 150 yards square, in which lie the temple and its magazines and other storerooms and dwellings, the town had spread outside the protection of its walls. A short distance to the north lies the New Kingdom Egyptian cemetery, and beyond this is a wide area covered by ancient remains, most of which appear to belong to a Sudanese culture of which little, if anything, appears to be known at present. Although the town now lies on the left bank of the river, excavation has shown that very probably it once lay on an island, the main channel running between the left bank and the town itself, giving it an admirable position for the control of river traffic. Some traces of the original landing stage have been discovered.

AMARAH WEST: EAST SIDE GATE WITH FORECOURT SHOWING FLOOR LEVELS OF DIFFERENT PERIODS.

The main work of the first season's excavation has been the examination and recording of the temple, which lies in the north-east corner of the enclosure, and consists of a forecourt, peristyle, hypostyle hall, and sanctuary area. The forecourt is built outside the north wall of the town, and in it, flanking the entrance, are pits in which were found the stumps of ancient trees still standing three feet high, two columns, and parts of two large stelæ built into niches, and bearing duplicates of well-known texts, in which Rameses II records his marriage with the daughter of the King of the Hittites and a dream in which the god Ptah appeared to him. In the Hypostyle Hall the twelve columns still stand some 9–10 ft. high, and here some of the most valuable discoveries of the season were made. Among these are the large hieroglyphic stelæ, which form a feature of the exhibits now at University College, while the walls were inscribed with scenes of a religious nature and with incidents from the Syrian wars of Rameses II, including an interesting view of a Syrian town, of which the walls are being undermined by Egyptian sappers. The most important discovery, however, and one which will prove ultimately of the greatest interest, both geographically and historically, is a long list of more than two hundred names of Syrian and Sudanese towns and peoples who owed allegiance to Rameses II. This list occupies the lowest register of all the walls of the Hypostyle Hall, and is the longest discovered in recent years. More than half the Syrian names have not occurred previously in hieroglyphic, and new identifications have been made, including what is probably the name Jericho, now appearing for the first time in an Egyptian text.

Beyond the Hypostyle is a small vestibule remarkable for the fine quality of many of its reliefs; and finally is the Sanctuary with side chambers and stone stairs leading to the roof.

The excavations have shown that the temple in its present form was built by Rameses II, but it was not completed until the sixth year of Rameses IX, some 140 years later. In its original state the temple consisted of the area covered by the Hypostyle and the present Sanctuary, which could not have existed then in the present form, as the entrance was on the south. Later, the Peristyle was added and acted as the Sanctuary. Later still, the entrance on the south was blocked up, a new gate was cut through the north wall of the town, and the original Sanctuary at the north end was pulled down and was rebuilt as the present Peristyle, while the forecourt was built outside the town to protect the new entrance. Occupation of the town goes back to at least the reign of Sethos I, father of Rameses II, and it is possible that the earliest occupation of the site dates so far back as the reign of Hatshepsut and Tuthmosis III in the Eighteenth Dynasty.

Owing to the exceptional height to which the walls now stand, a height rare on an Egyptian site, the town will probably prove the most complete and bes preserved town of Pharaonic Egypt yet discovered On the historical side, inscriptions of no less than ten kings have been found with details of wars, the names of new viceroys of Ethiopia, new materia concerning known viceroys, and the important new lists of Syrian and Sudanese towns. On the archæological side, the most important discoveries are the remains of a hitherto unknown Sudanese culture, and in addition sherds of the recently discovered 'Saharan' civilization. Hitherto 'Saharan' sherds have been found only in Egypt near Armant and in the Sahara as far east as Selima Oasis. It has been presumed that the Saharan people came from the desert and made their way to Egypt from the south; but the precise point of entry into the Nile Valley was unknown. The discovery of sherds of this civilization at Amarah, which lies at one end of the shortest caravan route to Selima, would appear to indicate that the first place in the Nile Valley to be reached by this people has now been discovered. It may have been one of their important centres, a resting place after the desert journey. Future excavation may be expected to bring to light new facts bearing upon the history and character of the culture. The exhibits, thought to belong to the previously unknown 'Sudanese' culture, consist of a number of agate, flint and chalcedony arrow-heads together with some basalt axe-heads.

The excavations have been under the direction of Mr. H. W. Fairman. It is expected that complete excavation of the site will take at least four to five seasons.

ANGULAR DISTRIBUTION OF SUBMARINE DAYLIGHT

THE angular distribution of the illumination under water, and its variation with depth and surface light conditions, is of interest for several reasons. In the first place, a comparison of the actual distribution not very far below the surface with that which we would expect to find below a perfectly smooth water surface, with the given daylight conditions, would enable us to estimate the amount of scattering caused by the surface, and so to check Clarke's suggestion that the considerable extinction produced by a wind-ruffled surface is chiefly due to the formation of bubbles the chief action of which would be to scatter some of the light and increase its average obliquity. Secondly, by comparing the distributions at different depths, we could judge the relative importance of absorption and of scattering in the extinction of the illumination, since absorption by the water, by matter in solution, or by dark and opaque matter in suspension, would cause enhanced extinction of the oblique rays and render the average light more nearly vertical, while scattering by particles would render it more diffuse. Thirdly, from a knowledge of the polar distribution and of the vertical illumination as measured by a photometer with a horizontal window, we could calculate the total illumination, which is the determining factor in photosynthesis. The latter could be measured directly with a spherical photometer if such could conveniently be employed.

Important advances in our knowledge in this direction have recently been made by Pettersson and his co-workers, and the latest paper on the subject by Johnson and Liljequist* describes numerous experiments in Swedish waters with two types of photometer; in the first, an opaque disk mounted axially at a variable distance above a wide-angle photometer enables all light above any desired altitude to be screened off, and the effect of each altitude zone to be obtained by difference. In the second, the sensitivity of the photometer is limited to a comparatively narrow-angled cone, the axis of which can be directed in any desired direction in altitude or azimuth, so that a complete polar distribution curve can be obtained.

The results show that in sunlight and comparatively smooth water, under which conditions the majority of the tests were made, the under-water light is chiefly limited to a cone of rays the axis of which is near the theoretical direction of the direct sunlight. With increasing depth, the axis of the cone becomes more nearly vertical, and its angle increases, the first effect being due to absorption and the second to scattering. The former, however, seems to be much the more important agent in the extinction. The authors also give figures for the ratio total/vertical illumination. This naturally falls as the light becomes more nearly vertical, either due to increasing solar altitude or to increase of depth of immersion. The authors' figures range from 1·23 to 1·51. H. H. P.

AMERICAN SPECIES OF CREPIS

E. B. BABCOCK and G. L. Stebbins, jun., have published in a Carnegie Institute of Washington iblication in 1938 a comprehensive survey of the merican species of *Crepis*. About a hundred pages e devoted to the descriptions of species, including ys to species, sub-species and apomictic forms ithin the species. The types described fall within velve groups derived from twelve endemic diploid ecies in each of which $x = 11$, and which are obably all derived by hybridization and polyploidy om Old World species with 4 and 7 pairs of chromo-mes. It is suggested that the former arose in stern Siberia in the warmer middle and late ertiary times.

The diploid species occur in circumscribed areas, eing limited mainly by climatic, though in part by laphic factors. The *Crepis runcinata* group differs om the other species groups by being entirely iploid and sexually reproduced; evolution within his species has apparently been by mutation and ther agencies, followed by selection in response to limatic and edaphic influences; the extreme types how intergrading and are interfertile, so that all are ncluded within the *Rassenkreis* of the single species. he other species show evolution mainly by polyloidy. The 'gigas' autopolyploids show similar istribution to the parent diploid, whilst allopolyloids, with characters intermediate between the arent species, are also more tolerant of climatic and daphic factors than either parent and consequently end to have a wider range. With hybridization there s a strong tendency for the sterile intermediate forms o be maintained by apomixis; such apomictic forms re often sufficiently definite to warrant separate lescriptions and keys for identification. The discussion of the behaviour of the species showing polyploidy and apomixis includes comparison with other genera known to behave in a similar manner.

The whole survey is very complete, and it is of great interest to have the distribution of the species mapped and discussed in relation to the climatic changes since the probable time of origin of the species. The wider distribution of the polyploid types indicates the greater tolerance of these to factors, which have presumably exterminated the diploids except from localized centres. This history of the Crepis flora and the preference of particular species for certain climatic and edaphic conditions may enable this genus to serve as a guide in further studies of the development of the present day flora.

The use made of structural features in estimation of polyploidy is worth mention. In many cases the average length of the guard cells of stomata from fully developed basal leaves gives a good guide as to the degree of polyploidy, though care has naturally to be exercised where hybridization has involved species with different initial size of guard cells in the diploid species. It was also found that pollen grains from diploid forms are approximately uniform in size and have three germ pores, whilst those of tetraploids are also uniform, some being predominantly three-pored, some four-pored. Triploid and pentaploid forms have markedly irregular pollen, with at least some four-pored grains. Thus differentiation between adjacent chromosome numbers, 22 from 33 or 44 from 55, may be drawn from examination of pollen, whilst distinctions between 22 and 44 or 33 and 55 chromosome types is obvious from the size of the stomata.

MODERN METALLURGICAL RESEARCH

ON June 22, Prof. F. Wever, of the Kaiser Wilhelm Institute für Eisenforschung in Düsseldorf, delivered a lecture at the Royal Society on "The Development and Present State of Modern Metallurgical Research". The lecture was one of those arranged under the scheme for an exchange of visits between representatives of the Royal Society and the Kaiser Wilhelm Gesellschaft, but it was clearly impossible in the space of a single lecture to deal with such a wide field as the title indicates, and actually Prof. Wever confined his attention to certain aspects of research on the structure and constitution of alloys and the transformations that influence them.

In a brief review of the early development of the basic methods of metallographic investigation, he paid tribute to the German, French and British men of science who were the pioneers in microscopy, thermal analysis and the construction of constitutional diagrams. In this part of the lecture his theme was that microscopic examination reveals the arrangement of the crystals in solid metals, thermal analysis enables the changes which affect this to be studied, while the application of the laws of heterogeneous equilibrium to co-ordination of the data obtained by these methods results in the construction of diagrams which represent the relations between constitution on one hand and composition and temperature on the other.

After a brief reference to the more recently developed study of metals by means of X-ray analyses, which enables the arrangement of the atoms in the crystals to be ascertained, Prof. Wever went on to deal with modern investigations on the kinetics of the transformations in solid metals. This is a field of research with which he has been closely associated, and most of this part of the lecture was concerned with the work of his colleagues himself. As investigations of this kind have confined to the study of the transformation occur in steel during cooling at differe attention was confined to the effect of cooling on the temperature of the progress of these changes at diffe temperatures below the critical range, and the structures produced in steels of different carbon content cooled at different rates or allowed to transform at different constant sub-critical temperatures.

Since the investigations of Dejean in 1917 and Portevin in 1919, it has been known that a progressive increase in the rate of cooling results in the first place in a gradual lowering of the normal changes, and in the second place, when a certain critical rate is exceeded, in the discontinuous depression of the changes to a lower temperature at which martensite is formed. Researches carried out since 1930 in the Kaiser Wilhelm Institute have contributed to present knowledge about the various changes and the relations between them. It has been shown, for example, that once the rate of cooling is sufficiently rapid to prevent any changes taking place above the martensite point, further increase in the rate of cooling does not produce further lowering of the martensite change. Thus a line may be drawn in the iron-carbon diagram to indicate the temperature at which the martensite change begins in steels of different carbon content, or a three-dimensional diagram may be drawn to show the relations between carbon content, rate of cooling and the temperatures of the transformations. It has also been known for some time that when steel is cooled to about 500° C. at a rate that suppresses the normal change, and is then cooled more slowly or maintained at constant temperature, an intermediate transformation occurs. The investigations with whi Prof. Wever has been associated indicate, howev that this intermediate transformation may al proceed to some extent during continuous cooling certain rates. Thus by cooling steels at progressive increasing rates, three kinds of changes may obtained, namely, the normal, the intermediate a the martensitic.

By means of a magnetic balance, the progress of th normal and the intermediate changes at differe constant temperatures has been studied. This wo has shown that the rate of the normal austenit pearlite transformation increases to a maximum the temperature at which it is caused to take pla is lowered, but further lowering leads to a diminutio in the rate and it finally becomes extremely slow. characteristic of this change is that at all temperatur there is a period of delay before it begins. At tem peratures below that at which the normal chang can take place the intermediate change occurs. Th begins immediately, proceeds at a rate that become more rapid as the temperature is lowered, an continues to an extent that increases as the tempera ture is lowered. At still lower temperatures th martensite change takes place with great rapidity and investigations on iron-carbon-nickel and iron carbon-manganese alloys have shown that th martensite change in carbon steels corresponds to th $\gamma \rightarrow \alpha$ change in iron-nickel or iron-manganese alloys

---

FISSION OF URANIUM NUCLEI

PROF. OTTO HAHN of the Kaiser Wilhelm Institut für Chemie, Berlin-Dahlem, was guest lecturer, on the invitation of the Royal Society, at the Royal Institution on Friday, June 23. Prof. Hahn's subject was "The Fission of Uranium Nuclei by Neutrons", and his account was chiefly historical. As the first definitely to establish the production of elements of medium atomic weight (fission products) when uranium is bombarded by neutrons, Prof. Hahn naturally confined himself mainly to describing the chemical method of investigation used by his colleagues and himself.

He described in detail how, in the process of confirming and extending the earlier investigations of Fermi and Curie and Savitch, Dr. Strassmann and he were forced to conclude that short-lived isotopes of barium and lanthanum were produced from uranium. These bodies could be separated from radium and actinium isotopes, but not at all from inactive barium or lanthanum, respectively, either by fractionation or by chemical means. Meitner and Frisch discussed these results in terms of division of the heavy nucleus into roughly equal fragments and Frisch showed, for the first time by a physical experiment, *that* the predicted large amount of energy is released in the act of fission. Thereafter, d Prof. Hahn, the whole subject was widely d in a great many laboratories throughout the In his own laboratory, the chemical investi- was continued and the production of fission product together with stron- stablished. The active barium and this showing, arise chiefly as decay products following xenon and caesium isotopes.

Up to this point, Prof. Hahn had described only previously unknown activities, but he went on to show how first one and then another of the so-called trans-uranic elements, postulated to explain most of the early work on the uranium disintegration, were proved, by purely chemical means, also to belong to the middle, rather than the end, of the periodic table. This was established by physical methods in other laboratories; but his own experiments had carried the matter further in one particular respect. After a great deal of labour, he had been able to show that the eka-iridium of the earlier classification contained molybdenum as well as tellurium—even though the half-value periods of the two active isotopes were distressingly similar! There remained only the task of applying the same methods of exact chemistry to the other activities which had not so far been studied, Prof. Hahn said, for his own contribution to the problem to be complete.

In the discussion which followed this most interesting lecture, Prof. Niels Bohr gave an account of the theoretical treatment of the fission problem recently undertaken by Dr. J. A. Wheeler and himself in the United States, and further contributions were made by Prof. M. L. E. Oliphant, Dr. E. Bretscher, Prof. G. P. Thomson and others.

Dr. Bretscher mentioned the results of preliminary experiments using large quantities of lead tetra-ethyl, which appear to show that fission occurs (though with a very small cross-section) with lead under fast neutron bombardment.

UNIVERSITY EVENTS

BELFAST.—Dr. R. H. Sloane has been appointed ecturer in experimental physics and Mr. G. Williams as been appointed lecturer in zoology.

W. R. Crawford has been approved for the degree f D.Sc. in mechanical engineering.

CAMBRIDGE.—Prof. D. M. S. Watson, Jodrell pro-essor of zoology and comparative anatomy, Univer-ty of London, has been appointed to give the Herbert Spencer Lecture in Trinity term, 1940.

EDINBURGH.—Mr. James Brough, of the University f Manchester, has been appointed lecturer in the logy of vertebrates in succession to Dr. C. H. Donoghue, and Mr. J. E. G. Raymont, of University lege, Exeter, has been appointed lecturer in the logy of invertebrates in succession to Dr. Peter y.

GLASGOW.—At Commemoration Day on June 21, the norary degree of doctor of laws was conferred on following, among others: Sir Andrew Duncan, airman of the executive committee of the British Iron and Steel Federation; Prof. W. J. Goudie, emeritus professor of the theory and practice of heat engines, University of Glasgow; Prof. I. M. Heilbron, professor of organic chemistry, University of London; J. McFadyen McNeill, naval architect, Glasgow; Prof. F. J. M. Stratton, professor of astrophysics, University of Cambridge; Prof. G. G. Turner, professor of surgery, University of London.

LEEDS.—Dr. M. G. Evans has been elected to the chair of physical chemistry, in succession to the late Prof. H. M. Dawson (see p. 15).

Dr. R. G. S. Hudson has been elected to the chair of geology which will become vacant on the retirement of Prof. A. Gilligan at the end of the present session (see p. 16).

Dr. J. B. Speakman has been elected to the chair of textile industries in succession to the late Prof. A. T. King (see p. 15).

The following appointments have also been made: Mr. Frederick Whalley, as lecturer in anæsthetics; Mr. Herbert Agar, as tutor in obstetrics and gynæcology; Mr. A. Stewart Johnstone, as lecturer in radiology; Mr. R. V. Riley, as research assistant in the Fuel Department.

LONDON.—Prof. Frank Horton, University professor of physics at Royal Holloway College, has been elected vice-chancellor for the year 1939–40.

Mr. Harry Stobie has been appointed, as from October 1, to the University chair of dental surgery and pathology tenable at the Royal Dental Hospital of London School of Dental Surgery. From 1932 until 1936 he was postgraduate instructor in oral surgery at the Royal Dental Hospital and since 1930 he has held the part-time posts of honorary dental surgeon, dean and director of teaching, and lecturer in dental surgery and pathology at that hospital.

Dr. Harold Heywood has been appointed, as from October 1, to the University readership in mechanical engineering tenable at the Imperial College of Science and Technology. From 1936 until 1938 he was lecturer in mechanical engineering at the City and Guilds College and since March 1938 he has been senior research officer at the British Coal Utilisation Research Association.

SCIENCE NEWS A CENTURY AGO

Equipment of Magnetic Observatories

THE study of terrestrial magnetism, which had made great strides in the early part of last century through the work of Hansteen, Gauss, Humboldt, Sabine and others was advanced another stage by the dispatch in 1839 of an expedition to the Antarctic under the command of Capt. James Clark Ross, for whom the Admiralty had fitted out the *Erebus* and *Terror*. The *Athenæum* on July 6, 1839, referring to this said: "We long since announced that a naval expedition was about to proceed to the Antarctic Seas, for the purposes of magnetic research and observation. In consequence the Royal Society have resolved to address a letter to such foreign societies as were most likely to take an interest in the subject, calling on them to aid, as far as possible, in executing a concerted system of observation". The *Athenæum* then printed the letter of the Royal Society which said that "Her Majesty's Government has ordered the equipment (now in progress) of a naval expedition of discovery, consisting of two ships, under the command of Capt. James C. Ross, to proceed to the Antarctic Seas for the purposes of magnetic research and also the establishment of fixed magnetic observatories at St. Helena, Montreal, the Cape of Good Hope, and Van Dieman's Land having for their object the execution of a series of corresponding magnetic observations during a period of three years. . . . The Court of Directors of the Honourable East India Company have also in compliance with the suggestion of the Royal Society, resolved to establish similar observations at Madras, Bombay, and at a station in the Himalaya Mountains. . . ." The communication was accompanied by a report made to the Council of the Royal Society by a joint committee of physics and meteorology. It was intended that a series of meteorological observations subordinate to, and in connexion and co-extensive with, the magnetic observations should be made.

Ross's expedition was a very successful one, and he penetrated to within less than twelve degrees of the South Pole. The Royal Geographical Society awarded him a gold medal in 1841 and after his return home in 1843 he was knighted.

Prevention of Steam-boat Accidents

IN consequence of the numerous accidents to steam vessels a century ago, the Government appointed Captain Pringle and Josiah Parkes to report on the causes and the prevention of such accidents. The first part of their report was printed in the *Mechanics' Magazine* of July 6, 1839. They recommended that a Board should be set up under the Board of Trade to register and classify all steam vessels, that surveyors should be appointed to inspect and report on the condition of vessels, that the Board should investigate all accidents, that an annual report should be made to Parliament on the state and progress of the mercantile steam marine, that instructions should be drawn up for the surveyors. that an abstract of the law relating to steam-boats should be placed in a conspicuous place in each vessel, that hulls should be surveyed half-yearly, that licences should be issued, and that the surveyor should ascertain that the safety valves in the boilers were the right size, and that no licence should be granted to vessels having the spindles or levers of the safety valves on deck.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ADVISER IN AGRICULTURAL BOTANY (MYCOLOGIST) in the University of Manchester—The Registrar (July 1).

LECTURER (WOMAN) IN NATURE STUDY AND EDUCATION in the City of Leeds Training College—The Director of Education, Education Department, Calverley Street, Leeds, 1 (July 3).

SUPERINTENDENT OF BALLISTIC RESEARCH in the Research Department, Royal Arsenal, Woolwich—The Under-Secretary of State (C.5), The War Office, London, S.W.1 (July 7. Quote appts. /150 A).

SUPERINTENDENT FOR A WAR DEPARTMENT EXPERIMENTAL ESTABLISHMENT—The Under-Secretary of State (C 5), The War Office, London, S.W.1 (July 7. Quote Appts./151 A).

LECTURER IN MECHANICAL ENGINEERING in the Heanor Mining and Technical School—The Director of Education, County Education Office, Derby (July 8).

ASSISTANT BOTANIST at the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1 (July 10).

ADVISER ON PLASTICS in the Directorate of Scientific Research of the War Office (and later for the Ministry of Supply when formed)—The Under-Secretary of State (C.5), The War Office, London, S.W.1 (July 10. Quote Appts./153).

ASSISTANT LECTURER IN ZOOLOGY in the University of Manchester—The Registrar (July 12).

ASSISTANT LECTURER IN GEOLOGY in the University of Leeds—The Registrar (July 12).

PROFESSOR OF CHEMISTRY in the University of Aberdeen—The Secretary (September 16).

PROFESSOR OF ENGINEERING in Auckland University College, New Zealand—The Secretary, Universities Bureau of the British Empire, 88A, Gower Street, London, W.C.1.

CURATOR OF THE PITT-RIVERS MUSEUM in the University of Oxford—The Registrar.

SCIENCE IN MODERN AGRICULTURE

IT is now twenty-nine years since the great forward step was taken which for the first time made agricultural research on any important scale possible in Great Britain. In 1910 Mr. Lloyd George set up the Development Commission, charged with the duty of developing agriculture and provided with an endowment fund which avoided the necessity of asking Parliament for money each year: it was thus able to take long views and to carry out important work which might otherwise have been impossible.

The wisdom of this method has been fully justified by the events of the succeeding years, and the twenty-eighth report of this Commission* now issued shows a remarkable range of activities, and a gratifying number of successful achievements of which all concerned may well be proud. The magnitude of the operations may be judged from the fact that the expenditure during 1937–38 amounted in all to £740,466, as compared with £641,126 in 1935–36. Of this sum £131,555 was devoted to fisheries, £2,300 to land reclamation, and £606,611 to agricultural and rural industries.

About £500,000 was in 1937–38 expended under the heading "research", the largest single item being the purchase of an estate at Compton for the provision of facilities for experiments, by the research institutes on livestock, which at present are difficult to carry out. The estate comprises 1,500 acres of easily farmed land on a chalk subsoil, and the herds include nearly 400 pedigree cattle and 450 pedigree pigs. The total price paid for land, buildings, equipment and livestock was £74,995. Nearly another £40,000 is to be expended on further developments.

A full account of the work on foot-and-mouth disease is given. This is one of the most serious and costly troubles in modern agriculture, and at present the only method known of dealing with it is to slaughter at once all infected animals. Slaughter is now compulsory; but of course compensation has to be paid to the owners, and the cost is very high. Successive ministries have ordered inquiries and carried out some investigations, and since 1924 a sum of about £200,000 has been spent on this side alone. In these circumstances, it is really distressing to read that until recently the study of the disease was only on a temporary basis: that "changes in the temporary scientific staff employed—changes due, in part at least, to the resignation of young workers seeking more permanent employment than could be offered by a committee constituted for a temporary inquiry—not only made the work very costly, but created something of a 'hope deferred' complex in those, including the commissioners themselves, who were responsible for expenditure". This happened, not as one might think, two hundred years ago, but in 1933! One wonders what is the use of our costly educational system that produces a community in which such complete disregard of the need for scientific investigation is possible. Happily this particular difficulty is now overcome and the investigation is to be put on a permanent basis.

A large part of the Commissioners' expenditure is on the agricultural research institutes at Rothamsted, Cambridge, Oxford, Aberystwyth, Aberdeen, Edinburgh, East Malling, Shinfield and other centres where the different branches of agriculture are shared out, each institute being responsible for a particular set of subjects. The arrangement works well, and the cordial relations between the staffs of the institutes on one hand, and the Development Commission, the Agricultural Research Council and the Ministry of Agriculture officials on the other, ensure adequate treatment of all the subjects. The general rule is that the Commission finds most of the money for annual maintenance and up to fifty per cent of approved capital expenditure, the institutions having to find the remainder.

* Development Commission. Twenty-eighth Report of the Development Commissioners being for the Year ended the 31st March 1938. Pp. 184 (London H.M. Stationery Office, 1939.) 1s. net.

The Development Commission spends its money wisely, but it is not the only body financing agricultural research. The Land Fertility Committee, the Sugar Commission, the various marketing boards all spend or can spend money under this name. In this awakening interest in agricultur history is repeating itself: "The farming tribe' wrote Arthur Young a hundred and fifty years ag "is now made up of all ranks, from a duke to a apprentice". So the promoters of agricultur research are in our time widespread and numerou Unfortunately, apart from the Sugar Commissio the so-called research is not infrequently n research at all, and indeed the effect of one of the bodies has been to put an end to some work permanent value that was being done. Happil the Agricultural Research Council is gettin into its stride, and when it is fully functionin it will prevent some of the wastage still liab to occur.

INTEGRATION IN THE CENTRAL NERVOUS SYSTEM

The Form and Functions of the Central Nervous System
An Introduction to the Study of Nervous Diseases. By Prof. Frederick Tilney and Prof. Henry Alsop Riley. Third edition. Pp. xxxvii+851. (London: H. K. Lewis and Co. Ltd., 1938.) 50s. net.

IN no part of the body is the relation of form and function so clear as in the central nervous system. Modern neurology owes its present position to advances in knowledge which have come from many sources. Comparative anatomy has shown clearly how the brain has altered and increased in size with the gradual evolution of the mammalian series, and the addition of new centres to the primitive brain can usually be correlated with changes in the habits or reactions of the new species. Anatomists have aided in the understanding of the human brain by two further lines of approach. Embryological investigation has helped in outlining the various components of the brain and, by a study of the gradual myelinization of tracts, has correlated structure with function. Finally, histological investigations iave shown that different parts of the nervous ystem contain highly differentiated cells, and ortical areas outlined by histological means ave been found to subserve different activities. n the other hand, detailed study of the functions the central nervous system has helped, in ny instances, to a clearer understanding of the ucture—study based both on physiological eriment and on clinical observation of patients rganic nervous disease.

Profs. Tilney and Riley, in their book, founde on a clear understanding of this important relatic of form and function in the nervous system, hav provided a model for a text-book, a model whic might well be copied for other systems in the bod Physiology and anatomy used to be regarded b students as two widely separated subjects. Th book provides detailed anatomical and histologic descriptions of the various component parts the nervous system, associated in each instan with an account of the evolutionary and embry logical significance of that part and followed b an account of its function, based partly c physiological principles, but illustrated by clinic syndromes. Case reports, used throughout th book, indicate to the student how dependen diagnosis is on a knowledge of detail, and ser as an excellent introduction to the study neurology.

To a clear account of the spinal cord ar the simple reflex arc, the authors gradual add details of the higher structures of th primate nervous system, and the increasin complexity of the control of the simple reflex, b the addition of new association tracts, both sensor and motor, is easy to follow. The development the cerebellum and its function in the 'synerg regulation of muscular patterns' is particularly we described.

Perhaps the most interesting sections of th book are those dealing with the cerebral corte The evolution of the cerebral hemispheres is se in its highest form in the human brain, and, follo ing a full account of the cortical localization of bo notor and sensory functions, the authors discuss the welding of the various afferent stimuli into cognition, based on memory of similar sensory patterns previously received. From this cognition, they follow the development of motor incentive patterns leading to activity, personality and intelligence. The authors reveal themselves as followers of the 'behaviourist' school of psychologists, explaining individualism largely on the basis of previous experience. They show how the structure of the silent parts of the cerebral cortex might well subserve such a function, but the exact correlation here of form and function must await fuller clinical, or perhaps psychological, analysis.

A few minor defects detract little from the achievement of this book, which is now in its third edition, but may be noted for possible correction in the further editions that will be called for. It is doubtful whether the "venosity" of the blood, rather than its carbon dioxide content, can be considered the chief source of stimulation of the respiratory centre, and Cheyne-Stokes respiration can no longer be regarded as due to a "vascular spasm so affecting the respiratory centre as to cause its exhaustion".

The illustrations in the book are excellent. They show clearly the points referred to in the text and, by their number, aid the reader in following the complex pathways as they track through the nervous system. The photographs of clinical cases, however, fall short of the high standard set by the other illustrations. It would be a diagnostic feat to recognize Fig. 568 as a case of juvenile paralysis agitans, and a more typical picture of an acromegalic should not be difficult to find. The authors state that in this edition an attempt has been made to reduce the bulk of the book and certain sections have been eliminated. In a book of this size it is a pity that space could not be found for a more detailed account of the cerebrospinal fluid and of the syndromes related to the obstruction of the various components of the circle of Willis and other arteries supplying the brain.

These are, however, minor points. Profs. Tilney and Riley have produced a book which will remain a classic, a fine introduction to the intricacies of neurology for the student and an invaluable work of reference both for anatomical detail and as an aid to the clinician attempting to localize baffling physical signs. M. L. R.

A CENTURY OF BRITISH PHILOSOPHY

A Hundred Years of British Philosophy
By Dr. Rudolf Metz. Translated by Prof. J. W. Harvey, Prof. T. E. Jessop, Henry Sturt. Edited by Dr. J. H. Muirhead. (Library of Philosophy.) Pp. 828. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Co., 1938.) 25s. net.

THE prodigious output of philosophical literature in Great Britain during the last hundred years makes it difficult for one to attempt a thorough examination of the various currents cutting across the field of speculative thought. Such an attempt involves a mastery of the manifold windings of that thought itself and a spiritual acquaintance with its distinguished representatives. A British scholar might have found it difficult to undertake such a task: living in the very atmosphere he would have to analyse, he might feel perhaps a lack of perspective for an unbiased outline of the controversial object of his inquiry.

It was left to a German scholar to provide us with a detailed account of the development of contemporary British philosophy. Though his book was originally written in German for the benefit of his own countrymen, it has aroused the interest of the editor and publishers of the "Library of Philosophy" and it has prompted three eminent British scholars to undertake its translation as a pure labour of love. The English translation, which amounts to a corrected and enlarged version of the original edition, brings the bibliographies up to date and contains valuable additions of new material, such as the enlargement of the sections on the Oxford moralists and the Logical Positivists. All these facts speak for the excellence of this work, which can be recommended not only for the accuracy of its information, but also for the candid opinions expressed on the leading philosophers of our time.

There are two parts in this book. The first one deals with the older schools of thought in the nineteenth century, such as the Scottish philosophers, the utilitarian-naturalist thinkers, and the group interested in religious philosophy. Although these schools are known in their main features, the general reader will find a new interest in them on account of the fresh material introduced by the systematic treatment of all their individual representatives.

The main attraction of the book, however, is the second part, which deals with the recent schools of thought, and which covers nearly three quarters of the volume. Beginning with the revival of interest in speculative problems initiated by Coleridge, it brings us down to the present day, through a panoramic display of the neo-idealist movement, pragmatism, the older and the new realism, mathematical logic, the philosophy of natural science, psychology and the philosophy of religion.

The older group of British idealists, such as Coleridge, Carlisle, Hamilton, Grote and Jowett, paved the way for the introduction of the German masters into our own philosophy. With Green and Caird, the powerful momentum of the thought of Kant and Hegel communicated itself to a variety of group of thinkers. Towering above them is the outstanding figure of Bradley, who has exercised a profound influence on our generation. Bradley's construction of the world begins with immediate experience, in which are combined feeling, know-
ng and being. The categories with which
he mind tries to grasp reality are in them-
elves mere appearances, though they may have
place in reality as fragments of it. But, the
timate and all-embracing reality is the absolute
the spirit, which comprehends and completes
finite experiences and appearances, and which
y be known through the ascending degrees of
lity, each fragment of which is dovetailed in
rger one until the absolute is reached. Similarly,
the field of action the self-fulfilment of the
vidual makes him gradually conscious of the
lute through his assimilation of wider social
, the mutual relations of which account for
luties and obligations.

his absolute idealism, Bradley is followed by
im and Bosanquet, who defend thought as
hway to absolute reality. Closely related
this group are the Hegelians, like Baillie,
ne, Mackenzie, Muirhead and Smith. With
al idealism are connected the names of
-Pattison, Rashdall and Sorley. The
strain is also found in the works of
-Carr and Hoernlé, and especially of lead-
of science like Eddington and Jeans, who
onceive the world of matter as something
independently of the mind. Compared
e dogmatic pronouncements of their
stic predecessors fifty years ago that
one was real, this attitude is particularly
. It is fair to add, however, that all
do not share these views. Writers like
the realist thinkers attempt a different
ion of the physical world.

The antagonism between spiritualism and materialism is more pronounced in the controversies about the philosophy of animate Nature, which keep alive the old feud between vitalists and mechanicists. The latter favour the view that life is a by-product of blind processes of dead matter; while the former maintain that life is something fundamental and creative, exhibiting its own purposes and ends. Hogben believes that there was never a time when biologists entertained more confidence in the usefulness of classical physico-chemical methods as instruments for arriving at predictable conclusions about the behaviour of organisms. Woodger goes even further by applying to the study of biological questions physical methods and an appropriate notation of mathematical logic leading to a gradual displacement of the notion of 'stuff' by that of 'system'; so that the notion of protoplasm or living matter will have to go the way of hereditary substance, if the biologists can learn to think of cells more in terms of systems and less in terms of stuff.

Against these mechanistic views, Thomson and J. S. Haldane claimed the independence of biology from physics, while admitting that the advances of physics during the present century have made it much easier to realize the true relations between these sciences. Thomson defended a "methodological vitalism" in which the physico-chemical phenomena of living organisms and groups cannot find a complete explanation without the biological concept of the organism as a historic being in which a racial as well as an individual past lives. J. S. Haldane went much further in maintaining that the mechanicist conception has been upset by the discovery that atoms are not mere inert elastic bodies, but centres of intense specific and persistent internal activity, and that on this internal activity their physical and chemical properties depend. Atoms seem now to have properties similar to those which are attributed to living organisms as co-ordinated wholes. Hence, if biology may retain the old physical and mathematical conceptions for practical purposes, the more fundamental of these very conceptions are assuming characters similar to those of biology. It may be added here that a remarkable feature of the philosophy of both these eminent representatives of vitalism is the indispensable part which God plays in their world-view.

It is as a reaction against idealism that the realist movement began in 1903 with Moore's famous essay "The Refutation of Idealism". In his defence of the objectivity of the external world, the existence of values and the external character of the relation between subject and object, Moore was soon followed by an increasing umber of thinkers such as Russell, Johnson, oseph, Ross, Price, Wilson and especially Alexnder, Lloyd Morgan and Broad. With these st three thinkers is connected the theory of mergence, which develops the view that physical vents manifest an ascending hierarchy of kinds of elatedness in the case of the various strata of xistence. Emergence is the explanatory principle hich accounts for every advancing stage of comlexity into the psycho-physical world. The echnical aspect of Lloyd Morgan's world-descripion is supplemented by Alexander's view that mergence stirs the spatio-temporal ultimate tuff of reality and thus produces in succession the arious ontological details of the world, from the tomic events of the physical nature to the mergence of deity.

A different realist strain pervades the conceptions of Russell and Whitehead, with whose names s connected the epoch-making "Principia Mathematica". This work crystallized the long controversies on the significance, the methods and the utual relations of mathematics and logic. It is lso a permanent source of inspiration to a score f logicians like Wittgenstein, Stebbing, Ramsay, Braithwaite, Heath, Mace and others. Russell's pistemological realism, however, becomes a neutral monism' in so far as it considers the ltimate stuff of reality as neither mental nor aterial, but neutral; while his analysis of our omplex experience breaks it into 'atoms' and has o be expressed as a 'logical atomism'. Whitehead's hilosophy becomes also a kind of monism with is explanation of the dynamic effort of the world passing into everlasting unity, and of God's vision ccomplishing his completion by absorbing the world's multiplicity of effort.

It cannot be said that all realists agree about the various problems of philosophy; some of them even go dangerously near idealism, in spite of common attitude to the fundamental problem of knowledge they profess. It is difficult to see, however, how their generous efforts can bear fruit when one takes into account their tacit acceptance of Hume's criticism of the fundamental notions of philosophy. Without the secure foundations afforded by such notions as substance, causality and deity, it is almost hopeless to build permanent constructions on such vague conceptions as 'the ultimate stuff of reality', 'enduring events', 'emergent qualities' or 'progressive deity'. If we submit these conceptions to a destructive analysis, would we not run the risk of seeing them also dissolve into nothingness? Scepticism and realism cannot thrive together; and, after all, realism cannot expect to win the fight for supremacy by surrendering its best weapons before the battle is joined.

Various practical characteristics and national peculiarities stand out from a close study of contemporary British philosophy. Individualism, distrust for comprehensive systems, empiricism, optimism, and in some cases mysticism, are among the most prominent. The fusion of these qualities with the traditional British common sense, has promoted a friendly relationship between philosophy, religion and the positive sciences. Indeed, without the theoretical and practical data of the sciences and of religious experience, philosophy alone could neither undertake conclusively its scrutiny of reality, nor carry our minds to the highest flights of purposive thinking. There is no reason why philosophers should reject the conclusions of faith while they welcome the results of experimental science. The world-view of philosophy embraces every aspect of human activity. British philosophy will no doubt be judged by future generations according to its power to promote and maintain co-operation with both religion and science. The trend of English thought, as it is excellently outlined in the present volume, bears out this belief.

T. GREENWOOD.

MANAGEMENT THEORY AND PRACTICE

The Principles of Rational Industrial Management

By James J. Gillespie. Pp. xv+229. (London: Sir Isaac Pitman and Sons, Ltd., 1938.) 10s. 6d. net.

A BOOK which claims to be "the boldest and most vital contribution to management thought in the past decade" must expect to be judged by a high standard. Unfortunately, whatever may be the intrinsic merits of this study, it is decidedly marred by jargon which both obscures the meaning, and occasionally descends to the coining of words. Nor can it be said that the author contributes anything that is very novel to management theory or practice. The limitations of scientific management in the narrower sense have been widely recognized in recent years. The social aspects of management and the social responsibilities which industrial leadership involv are being increasingly recognized, as well as the service basis of industry in its truest sense. Whatever mistakes have been made in the past, and however far industry may need to go in the future to link up its economic and social functions, it is a large claim that rejects entirely the term 'scientific management' in the way that is done by Mr. Gillespie, and substitutes for it what he describes as 'rational management'. His claim is unlikely to be accepted without demur by many concerned with the theory or with the practice of management.

When this has been said, however, it must be admitted that the author has written a stimulating book. Those who have the patience and perspicuity to penetrate the jargon in which some of his chapters are clothed will find much to repay them. Without detracting from the value of the scientific method, Mr. Gillespie indicates its limitations, particularly in the analysis of phenomena which involve social and economic factors. The failures of scientific management indeed arise not so much from its methods or tools, as from the narrow outlook with which it has sometimes been applied. Mr. Gillespie shows very clearly the importance of the other elements which may involved in the situations with which managem in industry is confronted. He indicates, too, h much industry itself has to hope from advan in the social sciences, as well as from the utilizat of the physiological and psychological d acquired, for example, by such investigations those of the National Health Research Board the National Institute of Industrial Psychology

The author includes a highly suggestive sect on leadership and lays a timely emphasis on importance of the principle of authority a obedience in management—not only the obedie of authority by employees, but also the obedience management itself to the whole purpose wh industry is serving, no less than to the regulati laid down by itself. Mr. Gillespie undoubte writes with vision but the book would have gai in value not only by some attempt to avoid jarg but also if the numerous cross-references to found in some of the chapters had been collec in a systematic bibliography as a basis for wider reading which the volume might stimulate.

GRAHAM LAND

outhern Lights
e Official Account of the British Graham Land
pedition 1934–1937. By John Rymill, with
o Chapters by A. Stephenson, and an Historical
roduction by Hugh Robert Mill. Pp. xv+296
0 plates. (London: Chatto and Windus, 1938.)
6d. net.

OUTHERN LIGHTS" is the record of just over two years' work in the Falkland ids' Dependency of South Shetland by an dition which was probably the largest in the nt style, wherein every member is a volunteer often a material contributor to the expedition.

reat value of the book lies in the amount of of method contained in it and in the stration of the manner in which experience, ought and choice of the correct means can the success of polar journeys. In addition, irectly emphasizes how such a mode of ch will avert 'adventures', so many of it may be suggested, are induced by those perience them.

ugh it may be labouring a well-recognized t is as well to emphasize the fact that in of work, aerial survey, valuable as it is, supported and checked by ground work, is demonstrated almost with violence by the contrast between the present map of Grah Land and its more immediate predecessor. (Th is here, indeed, an aspect of the first principle warfare—that the final decision depends occupation by the poor infantry.) The sledg parties attained the success they deserved for th efforts in a country of almost unnatural savag and, it may be added, beauty.

There is naturally and properly no more th passing reference to the scientific results, and may look forward to the publication of them w interest. The finding of fossils in Alexande Land is of great importance and at once remi one of the collection made by the Nordensk expedition on the other side of the igneous ro which form the visible mass of Graham Land. is known that very substantial collections and d were acquired by the biologists, and it is to hoped that one or two of the fifty-two aeropl flights were devoted to elucidating the obsc problems connected with the breeding of crab-eating seal in the pack.

Although the style is rather pedestrian, Rymill is to be congratulated on the productio a very useful book and also for not having ador himself with laurels, or a cap and bells.

J. E.

FACTORS IN POPULATION GROWTH

he Natural History of Population
y Raymond Pearl. (University of London: eath Clark Lectures, 1937, delivered at the ondon School of Hygiene and Tropical Medicine.) p. xii+416. (London: Oxford University Press, 939.) 10*s.* 6*d.* net.

THE student of population problems has received recently many additions to his brary, and the appearance of yet another volume ight fail to arouse interest unless it contained new facts or presented the known facts in a fresh light. Prof. Raymond Pearl's book on "The Natural History of Population" may justifiably claim to do both. Although some preliminary results of the researches which are described have een published in reports of the Milbank Memorial Fund, no comprehensive account of the work which formed the basis of the author's Heath Clark Lectures in London in 1937 has been available hitherto, and it is to be welcomed.

This investigation of the prevalence and effectiveness of contraception in twenty-six American cities was based upon information obtained by medical officers from 30,949 women free from disease who gave birth to children in the obstetric departments of 139 hospitals in those cities during 1931–32. Unlike previous data on this question, the material is not biased by having been collected in birth-control clinics but, as the author has taken great pains to show, may be regarded as fairly representative of conditions in the urban population of the United States. It necessarily excludes, however, the histories of women who were infertile by reason of complete success of contraception or for other reasons, and the material is likewise overweighted by the more fertile women, but the latter defect has been overcome to some extent by separate treatment of the primiparous and multiparous groups.

Prof. Pearl approaches the general problem of fertility from the point of view of the biologist and biometrician, and he has not hesitated to include on his questionnaire and to reduce to numerical terms most of the important factors, no matter how intimate. Whether we like this or not, it is only by this means that the intellectual fog surrounding the real causes of the recent decline in the birth-rate is likely to be dispelled. It is necessary to remember, however, that answers to questions of this kind may not be true answers, and that the deviations from truth will not necessarily cancel out when mass statistics are prepared from them. Psychological factors such as personal pride may lead to conscious or unconscious exaggeration for some questions and to understatement for others, and the book leaves in the mind of the critical reader some doubt as to whether adequate allowance has been made for this. A probable understatement of the frequency of induced abortion is admitted and recognized, but the possibility of overstatement of their marital activities by the married persons who provided the information needs to be considered, before accepting the conclusion that the average chance for a woman of reproductive age that conception will result after a single attempt is as small as 1 in 250.

In the material analysed, about 46 per cent of the white married women admitted or were believed to have practised contraception. When divided according to economic status, the proportion increased from 30 per cent among the poorest group to 80 per cent among the well-to-do and rich. It is estimated that in the general population from which the sample was taken the proportion was 55–60 per cent. The class differences in fertility are similar to those met with in Great Britain, and it is concluded that the chief factors responsible for them are the increase with advancing economic position of (1) age at marriage, (2) prevalence of contraceptive efforts and (3) the effectiveness of these efforts.

The observed differences between the fertility of Negro, native born and foreign born white women cannot be explained satisfactorily by birth control, however, and the author's conclusion that the steady decline in fertility which recent years have witnessed within each class of the population is not due solely, nor perhaps even primarily, to the increase in conscious contraceptive practices, seems to be justifiable. The great changes in mode of life which have resulted from the present type of civilization must have affected the urge for reproduction in many ways, and may have produced an unconscious diversion into new activities and interests of a great deal of vital energy which was previously directed to this end. It may now be too late to prove for the white races how important a factor this has been in bringing about the great fall in the birth-rate, since the comparative data of fifty years ago are not available, and it may be that the only way of proving it lies in the application of Prof. Pearl's method of inquiry over a long period of time in some country where the process of 'civilization' according to the white pattern is only now beginning.

NEW RESEARCHES IN STEEL METALLURGY*

BY DR. W. H. HATFIELD, F.R.S.,

DIRECTOR OF THE BROWN-FIRTH RESEARCH LABORATORIES, SHEFFIELD

RESEARCH in steel metallurgy is directed in the main to three principal aspects: (a) elucidation and improvement of the processes of steel manufacture and manipulation; (b) investigation of the properties of steel under variable conditions approximating to those of service; and (c) exploration of the influence of added elements and of the effect of heat treatment in advantageously modifying the properties of steel producing those best required under (b). It n truth be said that great progress has taken under each heading of late years.

progress of steel metallurgy is perhaps d at one of its industrial maxima in the produced for the aero engine. Enterprising aginative engineers like Dr. Fedden with gine developments must, indeed, demand nd more of us in strength and reliability of materials, and such demands, as I hope I shal be able to show, have drawn us along from on development to another. It is instructive, fo example, to compare the composition, microstructure, and properties of a marine engine crankshaft made from ductile Siemens Martin steel, with a modern aero engine connecting-rod made fro alloy steel produced in the electric furnace (Fig. 1 and Table 1). Of course the former is a massive structure, not highly stressed, whilst the latter is small and light in construction and very highly stressed.

MANUFACTURE AND MANIPULATION

It will be appreciated that in studying the refining process the physical chemistry relates to very high temperatures. What are the actual reactions between the liquid metal and the superimposed liquid slag? The refined liquid steel is poured into the mould and freezes. Liquid steel being a solution of various elements or their compounds in iron, which by differential freezing solidifies into a crystalline mass quite heterogeneous in character, one of the principal studies of recent years has been the determination of the nature and degree of this heterogeneity as affected by process, composition and conditions of casting. Ingots of various sizes and shapes in various

---

iday evening discourse delivered at the Royal Institution steels have been sectioned and the implications of this heterogeneity in the forged or rolled product have been studied in order that the most suitable ingot as regards process, form and composition can be selected.

As a result of the reactions of the steel-making process, the liquid steel contains disseminated through it small quantities of oxides of silicon, iron, manganese and other elements, but during the cooling and freezing process these oxides coalesce and orientate themselves in well-defined design; along with these oxides are sulphides resulting from the sulphur content of the steel. Such oxides and sulphides form weakness transversely to the direction of forging and rolling, and any mitigation of the trouble by reduction of the oxide and sulphide content is much to be encouraged.

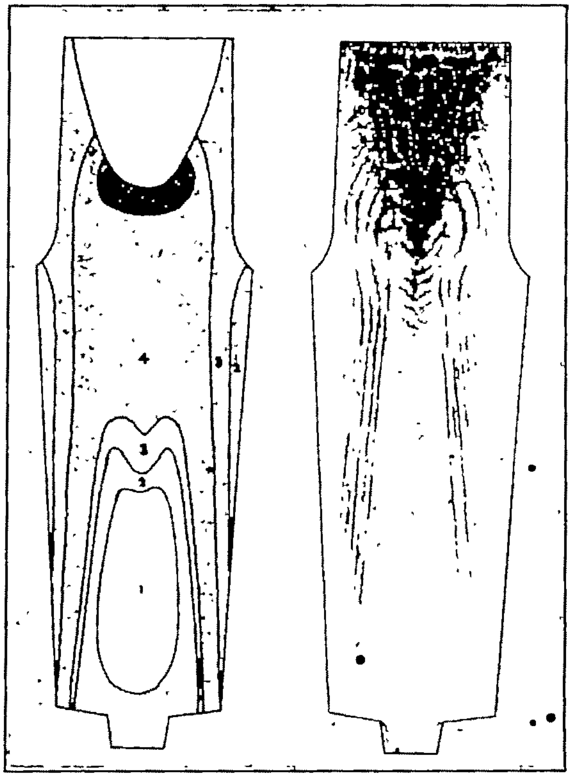
This problem is steadily yielding to inquiry and experiment, although the experimental difficulties are great. The compounds in equilibrium or indeed in existence at 1600° C. in the liquid phases are not necessarily those encountered at 15° C. Solubilities are different, and hence, for example, the difficulties of studying the solubility of gases. It is important to know the oxygen content and its condition in the liquid steel; one great step forward has been the development of the vacuum fusion method of determining the total oxygen in the final steel, but we have not as yet quite mastered the technique of determining the form in which the oxygen occurs. The nitrogen and hydrogen contents of steel are also having much attention, and these, particularly the hydrogen content, may prove of consequence.

In small masses, modern technique gives very good results as regards homogeneity, but if you pour 100 tons or 200 tons of liquid steel into a mould and allow it to freeze, the differential freezing produces a heterogeneity of a more serious order which is clearly transmitted in the structure of the final forging. If a large ingot is sectioned along its axis and the plane exposed is studied for variable composition and segregates, the nature of the result of the inquiry is indicated in Fig. 2.

Whether the ingot be small or very large, it has to be heated to a sufficiently high temperature for forging and/or rolling. Also steel in varying mass has to be reheated and cooled in the heat-treatment processes such as annealing, hardening, tempering and stress-annealing. Thus, much research has of late been devoted to studying temperature gradients within the mass with different rates of heating and cooling, the reason being that temperature gradients produce internal stresses under certain conditions high enough to produce rupture, and when of even much lower order may in part be permanent in character.

EFFECT OF TEMPERATURE ON THE PROPERTIES OF STEELS

Perhaps one of the most complex studies is that of the changing properties of steel with varying temperature. It is of the utmost importance to the engineer that he should know the stresses the material will withstand under such changing and different conditions. Important steam-raising and power-generating units operate at temperatures up to 500° C., whilst items such as exhaust valves, superheater and furnace parts operate at 700° to more than 1000° C. On the other hand, steels used in aeroplane construction and special engineering must encounter very low temperatures; indeed, for experimental work, steel has been supplied to operate at −180° C.



(a) (b)

Fig. 2.

180-TON INGOT SHOWING (a) ZONES OF VARIABLE COMPOSITION; (b) DISTRIBUTION OF SEGREGATES. (a) The lighter the zones the lower the percentage of the elements which were in solution in the liquid steel. (b) Streamers of segregates are shown.

This study includes a knowledge of the properties of steel at ordinary temperature and at the special temperatures after a lapse of time comparable with the later stages in the length of life of the part under service conditions.

To instance the nature of research in this field one must emphasize that, whereas until comparatively recent years the understanding of the mechanical properties of metals has been based upon rapidly applied stresses at the normal temperature resulting in destruction, as in the case of the well-known tensile, torsion, bending or notched bar impact tests, the experiments to which I am about to refer concern stresses of a known magnitude applied over long periods of time at temperatures well above the normal and in conformity with temperatures of service. Permanence of form and dimensions, except for elastic deformation under service stresses with a practical absence of plastic deformation, is fundamental to the successful operation of much modern mechanism, whereas the rapid destruction tests just referred to provide information of plastic deformation under rapidly applied stresses of sufficient magnitude to cause rupture, which has little bearing upon the problem of safety in design. The data really required concern the range of stress which can be safely carried without producing plastic deformation in excess of previously determined very small permissible values.

Nearly ten years ago I put in hand an experiment which is still proceeding. This experiment consists of placing a strip of steel in tension under a stress of 25 tons per square inch. The material was a old-worked austenitic steel with a limit of proortionality of 27·4 tons per sq. inch and yield oint of 77 tons per sq. inch. Since June 1929 e permanent extension has been *nil* within e accuracy of measurement applied, namely, sensitivity of 1/40,000 of an inch and a gauge gth of 8 inches. Clearly, if deformation is oceeding, it is at a less rate than 4×10^{-11} or 5,000,000,000 of an inch per inch per hour, and nay be claimed that evidence is still lacking of nge of dimensions in this case under a stress igh as 25 tons per sq. inch. The temperature his case is 23° C. and the data from the ordinary ile test broken at atmospheric temperature led the stress employed to be selected. The riment now constitutes a creep test over a d of 85,000 hours.

th the introduction of temperature above n values, this phenomenon of creep becomes inating one, and the problem is to determine stress which will not produce creep or nation beyond postulated values under the ions we are considering. The facts differ ifferent steels for the same ranges of temre and for different temperatures with the steel, and therefore only selected experidata can be given to illustrate the ena.

ke the range of steam temperatures and the behaviour of two steels, namely, bon steel and a similar steel containing molybdenum, at a temperature of 400° C., o tensile tests give the following values :

	0·5% Proof Stress (tons/sq. in.)	Max. Stress (tons/sq. in.)	Elong. (per cent)
Mild steel at 20° C.	20·25	34·1	40·8
" " 400° C.	16·2	32·54	38·5
Molybdenum steel at 20° C.	23·5	38·0	29·0
" " " 400° C.	20·5	36·7	30·0

If constant values of stress are applied t two steels at a temperature of 400° C. period of 1000 hours, and careful determi made of the effect of the loads, it will be fou deformation proceeds at stresses well bel tensile test yield point. With a stress of per square inch the mild steel creeps dur 24th to 72nd hour period at a rate of 26 inch per inch per hour, and even in the 5 hour period at a rate of $1 \cdot 4 \times 10^{-6}$; whi a stress of 7 tons per square inch creep in the 24th to 72nd hour period at a $1 \cdot 1 \times 10^{-6}$, and in the 500–1000 hour p a rate of 6×10^{-8}. The addition of moly to the other steel enables a stress of 15 t square inch to be sustained with a rate of $1 \cdot 25 \times 10^{-6}$ in the 24th to 72nd hour and so low a rate as $1 \cdot 4 \times 10^{-7}$ for the 5 hour period. Thus, it is shown that, experiments of this character, the influ added elements is determined as regards important characteristic of the material.

The results of experiments conducted peratures of 900–1000° C. over very long of time will be of interest. A heat-resistin that is, a steel having the necessary re to oxidation as well as some strength temperatures, containing carbon 0·21 p nickel 12·32 per cent and chromium 21·09 p was maintained under a load of 280 lb. pe inch for the period of 10,000 hours at The load produced an initial rate of cree diminished with time to a value of m which became constant after about 200 Over the whole period of 10,000 hours the permanently extended in length about (cent.

The microstructure in Fig. 3 (*a*) is tha test piece as not exposed to the high temp whilst (*b*) illustrates the change in structu the 10,000 hours exposure at 900° C. atmosphere ; (*c*) illustrates the structur the surface, and it is seen that oxidation h place, but must have been slowed up protective oxide formed during the expos

This experiment shows that with this ste these conditions the rate of creep does to a constant minimum rate, but that, creep or deformation under the applied str continues at that rate. Similar experiments indicate, however, that the course of this particular experiment is not always repeated.

Such long time tests are quite impractical as a means of comparing the creep properties of large numbers of alloys. This was foreseen many years ago, and a short time test, extending over a period of only three days, was devised, which is applicable to the whole range of temperature from 300° C. to 1000° C., and has been used on an extensive scale in the testing of many alloys. The applied stress is permitted to produce deformation over the first 24 hours not exceeding 0·5 per cent of the gauge length, but during the next 48 hours no further change in dimensions shall take place within the accuracy of measurement, which is to 1/40,000 inch. On a gauge length of two inches, this is approximately equivalent to one millionth of an inch per inch per hour. The maximum stress not producing a deformation in excess of that so postulated has been named the *time yield*, and produces data which can be interpreted usefully with the assistance of data for longer period and more sensitive experiments. Table 2 schedules results on different steels obtained within the steam practice range of temperatures, whilst Table 3 gives comparative data for a number of steels within the higher range of temperature.

TABLE 2. EFFECT OF COMPOSITION UPON 'CREEP' CHARACTERISTICS OF STEELS

Composition (per cent) C	Si	Mn	Ni	Cr	Mo	Time Yield (tons/sq. in.) 300° C.	400° C.	500° C.	550° C.
0·24	0·14	0·59	(0·08)	(0·04)	nil	12	7	3½	1¾
0·28	0·22	0·53	(0·16)	(0·11)	0·66	19	13½	8	3½
0·34	0·29	0·57	3·06	nil	nil	21	10	3¾	2
0·34	0·18	0·65	3·22	0·87	nil		10	3¾	
0·28	0·13	0·51	2·76	0·67	0·61	43	21	9¼	4
0·35	0·18	0·71	(0·22)	2·41	0 51	40	22	10	4
0·43	0·20	0·60	(0·21)	1 30	0·85	—	21½	7½	4

One important line of investigation concerns the effect of exposure to temperature for a long time upon the mechanical properties of the steels. Extremely important mechanical units have to operate for a life of many years at elevated temperatures, and owners are not very free in scrapping valuable parts so that tests can be made to see whether the mechanical properties of the materials are being maintained.

Some time ago we installed substantial furnaces for long-time experiments of this character and have many steels exposed, for example, at 400° C.,

TABLE 3. RESISTANCE TO 'SCALING' AND 'CREEP' STRENGTH OF SPECIAL STAINLESS AND HEAT-RESISTING STEELS.

	Scaling index 800°	900°	1000°	1100°	1200° C.	'Time Yield' creep value 400°	500°	600°	700°	800°	900°	1000° C.
Mild (28/32 ton) steel	84	250	—	—	—	8	4	1	400	—	—	—
13% chromium stainless steel	0 28	32	250	—	—	14½	5¼	1350	240	125		
3½% silicon—8% chromium steel		0·33	0·64	76	—	19	4	1	300	180	—	—
30% chromium steel		0·41	2·3	5·7	19	17	11½	1	320	350	200	70
18% chromium—8% nickel steel	0·12	6·7	175	750	—	12½	11	5	2	1000	200	70
13% chromium—14% nickel—3% tungsten steel	0·08	3·5	25	—	—	18	8	3¼	1¼	800	190	70
25% chromium—20% nickel steel		0·22	5·1	11	31	13	10½	3¾	1¼	900	250	70
23% chromium—12% nickel—4% tungsten steel		0·41	2·0	15	1,000	19	12	4½	1¾	1,200	280	90

"Scaling" index expressed in milligrams per sq. cm. increase in weight.
"Creep" strength expressed in tons/sq. inch above 1 ton and in lb./sq. inch below.

450° C. and 500° C. Each test piece is substantial in size and enables a very complete study of the material to be made. Samples of a particular steel are taken out after one month, six months, twelve months, and so on, and already valuable data have been derived.

We have already found that some steels maintain their properties; others, whilst maintaining their tensile test values, offer less resistance to notched bar impact fracture, and others by a type of precipitation proceeding even after twelve months exposure have a progressively increasing strength and a decreasing ductility. Tests done at normal temperatures after exposure are not an adequate indication of the actual properties at the elevated temperature at which they have been exposed, and therefore since the temperatures selected simulate service conditions, the mechanical tests are also being performed at these temperatures. In the main, the experiments to date indicate a more ductile condition at the temperature than in the cold.

EFFECTS OF ALLOYING OTHER ELEMENTS

The metallurgical processes in industrial use produce in bulk an *impure* iron, that is, mild steel, which is iron with a residual carbon content of 0·10–0·20 per cent and a residual manganese content of 0·40–0·8 per cent, having very useful mechanical and fabrication qualities for structural urposes, marine engineering and many other urposes. By increasing the carbon content the trength of the steel is increased and its ductility ecreased, but qualities suitable for rails, tyres r even tools are so prepared.

The multiplicity of alloys which it would be cessary to make to exploit thoroughly the sibilities of the influence of added elements is vious, and, therefore, it is clear that only the ge of the subject has yet been explored. Much cess, however, has been achieved.

High tensile steels are available through the luence of small quantities of added elements, the more outstanding advances relate to the uence of larger additions of the special elements. high percentage of nickel produces a steel a very low coefficient of expansion, whilst in percentages of nickel, manganese and mium enable steel to be produced with a coefficient of expansion comparable with of the aluminium alloys.

gh percentages of cobalt, or of nickel and inium, enable permanent magnets of amaz- high coercive force to be produced. The nce of small quantities of chromium and nium enable hardened surfaces to be pro- by the influence of ammonia at temperatures as 500°–550° C.

High manganese content produces a steel of excellent wearing properties under abrasion, whilst high chromium or high chromium and nickel contents produce a range of steels which are rust- and acid-resisting. Add to the last category other special elements and the interesting heat-resisting steels are produced which not only resist scaling at high temperatures, but have also considerable strength under such conditions.

Perhaps the most outstanding achievement of recent times is the development of the rustless and heat-resisting steel metallurgy. Brearley in 1913 had shown that a stainless knife could be made by hardening and tempering a steel containing 13 per cent of chromium. This led to the search for steel which was rustless in the ductile condition, and so the 18 per cent chromium, 8 per cent nickel, and the 12 per cent chromium, 12 per cent nickel, and other combinations were produced. Such steels are indeed stainless under normal conditions, and form the basis now of a great industry.

One is invariably asked, Why are the rustless steels rustless? The answer is, that they are cases of passivity, induced by composition and normal environment in the production of a passive external film. This is in part proved by the fact that under certain conditions local corrosion will take place even with so defined rustless steels, as a result of *shielding action*. Shielding action is the effect of a deposit of material resting on the surface of the steel, which by its presence partially or completely prevents free access of oxygen to this surface of the steel, and thereby retards or prevents the repair of any minor breakdown of passivity. It is obviously necessary, in order that corrosion should develop, that the shielding agent should not entirely prevent access of the corroding solution. Such a conception is in line with the explanation which Faraday advanced in 1836 in explanation of the chemically induced passivity in the case of ordinary iron surfaces; he visualized that "the surface of the iron is oxidized on the superficial particles of the metal and in such relation to the oxygen of the electrolyte as to be equivalent to oxidation." It was left to Dr. Ulick Evans to isolate such passive films.

The following experiment has reference to the gradual and visible thickening of this passive film under rather special conditions with time. In December 1924 (more than fourteen years ago), a cylinder of plain 18 per cent chromium, 8 per cent nickel steel was placed in a bottle of nitric acid of strength slightly higher than 1·20 sp. gr. After a year or two a clouding of the surface was noticed, and, accordingly, in June 1928 a second cylinder was immersed under similar conditions; again the same effect was noticed with the passing of time. In

June 1931 a further cylinder followed. These three cylinders have now been exposed for periods of 14 years, 10½ years and 7½ years respectively. The first is covered with a dark brown film, the second with a straw-coloured film, whilst the third as yet shows only a slight dulling of the surface. This evidently slower rate of film thickening, in the case of the third cylinder, may be due to its having a mirror finish as compared with a fine emery finish in the case of the other two cylinders.

The solutions were examined in August 1938, and from these figures the weight of iron and of chromium dissolved from the cylinders was calculated, and it was found that there was a deficiency of chromium in relation to the iron when the relative proportions in which these two elements were present in the steel were taken into account. It was then assumed that this *missing* chromium is present in the form of Cr_2O_3 in the films on the surfaces of the cylinders, and the amounts were calculated.

It is interesting to note that the calculated thicknesses of the films on the first two cylinders are not far removed from the value of about 4×10^{-6} which is obtained from the work of several investigators for the thickness of films giving a similar coloration. In the case of the third cylinder, the calculated film thickness is less than the minimum thickness required to give a definite coloration.

It was quite accidentally discovered that a cylinder of 13 per cent chromium steel which is apparently not affected by nitric acid but is soluble in sulphuric acid, became passive for long periods in sulphuric acid after immersion for a period in nitric acid. This observation was made some fifteen years ago and before we had obtained the interesting data from the three cylinders of 18/8 material. Evidence indicates that the corrosion-resisting properties of the rustless steels are due to the chromium facilitating the spontaneous production of a protecting film of the necessary characteristics for resistance, which film if damaged is spontaneously renewed.

Experimenting upon the basis of the rustless steel compositions, it has been found that by modifying the chromium and nickel and also by adding other elements such as tungsten, molybdenum, cobalt or titanium, steels are produced which maintain a reasonably protective film at temperatures even in excess of 1000° C., and also have useful strength.

THE ROYAL AGRICULTURAL SHOW

By Prof W. B. Brierley

IN English agriculture the "Royal Show" is the peak of the year, and the occasion in 1939 is of special significance as it marks the centenary of the Royal Agricultural Society of England. It is fitting, therefore, that the Show should be held during July 4–8 in the Royal Park of Windsor, and that the University of Reading, which increasingly plays a leading part in agricultural education and research, should have been invited to accept responsibility for the scientific exhibit. The exhibition in the building devoted to education, research and marketing was arranged by the Faculty of Agriculture and Horticulture of the University (including the National Institute for Research in Dairying and the British Dairy Institute) with additional exhibits by the counties of Buckingham (acting in co-operation with the Buckinghamshire Producers) and Northampton.

For many years, the scientific exhibit at the Royal Show has been of very high calibre, and this is all the more creditable when it is remembered that agricultural teaching does not lend itself to exhibition, and that agricultural research is of a somewhat plodding nature and that it possesses none of the more spectacular qualities of research in many other branches of science. Each year, however, it has become increasingly difficult to improve on the interest of former exhibits or to vary them in kind, and for the special occasion of a centenary show the young University of Reading was faced with an exceptionally difficult task. It achieved a notable success due, primarily, to two facts: first, the entire exhibit was arranged on the central theme of the progress in agricultural research and its application to practice during the last hundred years, and, secondly, the individual exhibits were merged in a common decorative scheme designed and produced by the School of Art of the University of Reading. The many scientific exhibits were excellent, but it was the happy marriage of science with art which remains the outstanding impression left by the scientific building.

In any scientific exhibition the benches are occupied by specimens, instruments, etc., but it is always difficult to know what to do with the wall space. Sometimes it is just left as a blank and rather depressing area; more usually it is filled with graphs, tabular or textual matter which few people look at and which frightens many people away. It is, however, in the efficient and attractive use of wall space that the artist can render such valuable aid and, in the Royal Show exhibit, probably more people looked at the walls than at the benches. The scientist gave specific information, but the artist gave the general mental impression which synthesized the data, and which remained when specific facts were forgotten.

All interested know of the serious reduction in the total cultivated area of Great Britain, the reversion of the relative importance of arable and grass, the fall in the cereal acreage, especially wheat, the partial replacement of the old root break and the appearance of the new sugar beet crop, and the increase in the acreage under potatoes and fruit, but few things could do more to bring home to the general public the reality of these changed conditions than the economics exhibit, with its pictorial representations in the form of large colourful wall panels occupying the centre of the building. Similarly, a number of smaller but very attractive panels depicted corresponding changes in the numbers of dairy cows, poultry and pigs, and the decrease in the numbers of horses and sheep. A further panel portrayed one of the most lamentable facts of British farming, the exodus from the land.

With the National Institute of Research in Dairying and the British Dairy Institute contributing to the exhibition, it was only natural that milk and milk products should occupy a prominent place. Their joint exhibit was designed to present a picture of the progress of dairying and dairy science during the last hundred years, and its success was very evident. Two flanking panels, '1839" and "1939", showed in vivid contrast the hange in the organization of the dairy industry uring this period, and a central panel indicated ndmarks in dairying; one very important landark being the foundation of the National Institete itself so recently as 1912. Other panels ustrated progress in more specific aspects of earch, such as the better breeding and feeding dairy cattle, vitamins in milk, and the value clean milk as food.

Cattle have always been recognized as important stock but, during recent years, the despised has also acquired merit and its numbers have espondingly increased. In pig breeding a basic or is accurate recording, and the importance of was well illustrated in a special exhibit.

lso, during recent years, the poultry industry, the Cinderella of agriculture, has developed rapidly that it now stands third in economic importance. An excellent exhibit, backed by mos attractive wall panels, showed this progress and demonstrated some of the changes in poultry husbandry and marketing which made it possible

But farm animals like human beings are heir to many maladies, and the veterinary scientis plays the same important part in agriculture that the medical man plays in human society. During the last hundred years notable progress has been made in this field, and this was portrayed in an interesting exhibit in which particular attention was given to tuberculosis, parasitic gastro-enteritis and contagious abortion.

An important line of research carried out at Reading is soil surveying, a science of pedology only some fifteen years old. This work was illustrated by some beautifully coloured maps and by the profiles of twelve different soils occurring in Berkshire and Hampshire. Somewhat related to this was an exhibit illustrating the Land Fertility Scheme. The Government's scheme came into operation in September 1937, and the work carried out under it has already given valuable insight into fertility problems as a whole and certain special problems in particular.

In all agricultural matters and problems we return inevitably to the soil. As St. Francis sang, "Praised be, my Lord, for our sister, Mother Earth, which doth sustain and keep us, and bringeth forth divers fruits, and flowers of many colours, and grass". But the soil is not just dead matter, a physico-chemical system for pedologists and chemists to dissect. It is a vast unexplored realm of living things, a land of Lilliput with teeming populations of microscopic plants and animals, eating, breathing, reproducing their kind, and fighting for existence in a struggle as relentless as any in our Brobdingnagian world. The most important of these soil microbes are the bacteria and fungi for, ultimately, all life and all living things are dependent upon them for existence. In two interesting exhibits, backed by decorative and informative wall panels, the story of these soil microbes was well told.

It would be almost impossible to construct any scientific exhibition relating to agriculture in which pointed attention was not given to the vital necessity of grassland improvement. Progress in this field was well illustrated by an exhibit "Two blades of grass where one alone was seen before", which showed clearly the improvement in the management of grassland due to the use of the best herbage plants and pedigree strains, aided by controlled cultivation, manuring and grazing.

A complete representation of a century's progress in arable crops would have been extremely interesting, but the difficulty of showing improvement in roots rendered such an exhibit practically impossible. There was, however, a valuable and finely staged exhibit showing improvement in cereals, which included mature growing plants, of varieties of wheat, oats and barley that were grown approximately a hundred years ago and an equal number of well-known modern varieties.

With the increasing recognition of the value of protective-foods, horticultural crops in many ways now rival agricultural crops in importance, and the value of scientific research in horticulture is rapidly attracting attention. Under modern competitive conditions high quality produce only is demanded, and this is unobtainable from neglected and pest-ridden orchards and gardens. This was exemplified partly in an exhibit designed to stress the differences between the old-fashioned ill-kept orchard and the modern plantation run on commercial and scientific lines, and partly in an exhibit of vegetables, salads and fruits grown in the intensively farmed area of Buckinghamshire.

Finally must be mentioned the garden in front of the scientific building, which was laid out by the University Department of Horticulture to a design prepared by the Department of Landscape Architecture. A magnificent centre bed displayed the carpet bedding fashion of a century ago, whilst two flanking beds showed a modernistic treatment.

The entire exhibition was a notable success, informative and stimulating in its portrayal of the interest of agricultural and horticultural research and of its value in practice, and not only colourful but also satisfyingly beautiful in the artistry of its design and production. The exhibit was worthy of the Royal Centenary Show and set a standard which it will not be easy to maintain.

OBITUARIES

Dr. W. M. Childs

DR. W. M. CHILDS, principal of University College during 1903–1926 and first vice-chancellor of the University of Reading during 1926–1929, died at his residence, Grimsbury Bank, Hermitage, Berkshire, on June 21, aged seventy years.

In the history of the modern English universities, no one has played a part corresponding at all closely to that of William Macbride Childs. With the exception of Reading, the universities which have arisen during the past fifty years have developed from earlier colleges, with an established tradition of teaching and research as the justification for their academic independence. But the whole history of the movement which created the University of Reading is comprised within a period of less than half a century. The institution to which Childs went as a lecturer in 1893 was little more than a centre at which work initiated by university extension classes could be carried to a further stage; it had scarcely the rudiments of an academic organization, and its financial resources were meagre and uncertain. It is the supreme distinction of Dr. Childs that he saw the possibilities latent in this small and anomalous institution, devoted his life to their realization, and impressed the stamp of his personality on the college and university which came into being through his efforts.

Childs was enabled to succeed in what seemed at first a hopeless task by the intensity of his belief in his ideals, and by his power of imparting his own convictions to others who could help him. He possessed the rare faculty of constructive imagination. To him, the ideal university was a community of teachers and students, informed by a life and spirit which transcended the achievements of individuals. From the pursuit of this ideal he never turned aside. But unlike many idealists, he had the habit of mind which finds pleasure in practical details, and his patience could never be exhausted. He planned every stage in the long process through which the college at Reading came to university independence. The addition of one department after another to the nucleus of a college with which his work began, the creation of an academic organization, the establishment of halls of residence for students, were all, to him, matters of intense personal interest. For thirty years he concentrated the abilities of one who was by nature a man of affairs upon the details which gave form and substance to an ideal.

In course of time, the influence of Childs' personality and work spread beyond the circle of his immediate associates. It was his devotion to his chosen task, and the transparent sincerity of his conviction that the creation of a university in Reading was a work which any man might be proud to advance, which brought to the college the endowments essential to its growth. On the general history of the modern universities, his influence, though indirect, was real. The most original part of his work at Reading was the establishment of a system by which all students not drawn from the immediate neighbourhood live in halls of residence. To-day, the value of life in a collegiate environment for students of a modern university is recognized everywhere. But when Childs conceived the idea of basing the University of Reading upon a residential system, little had been done in this direction elsewhere, and the opening of Wantage Hall in 1908 was the first effective demonstration of the fact that life under conditions similar to those which have prevailed for centuries at Oxford and Cambridge was possible for students of a modern university. It was not until 1926 that Childs' work was crowned by the grant of university independence to the college at Reading. But the opening of Wantage Hall, which symbolized his most significant contribution to the idea of a modern university, was probably the event in his career from which he derived the greatest pleasure, and it is the event which comes first to the memory of some, at least, of his associates on the morrow of his death.

F. M. STENTON.

Prof. A. E. Kennelly

WE regret to report the death on June 18 of Prof. Arthur Edwin Kennelly, emeritus professor of electrical engineering both at Harvard University and at the Massachusetts Institute of Technology. He had laboured for many years enthusiastically and successfully to further the interests of humanity by lightening manual and mental drudgery and promoting international co-operation for the interests of all. His work led him to associate with experimental and theoretical physicists, with mathematicians, inventors and engineers.

Kennelly was born at Bombay in India in June 1861 of British parentage. He was educated at private schools in Scotland, France and Belgium, and for four years at University College School, London. His first post was that of assistant secretary of the Society of Telegraph Engineers of London (now the Institution of Electrical Engineers). In 1876 he was a telegraph operator in England with the Eastern Telegraph Co. and in 1878 he was an electrician in Malta. In 1881 he was chief electrician in a cable engineering ship. In 1887 he went to the United States and became the principal electrical assistant to Thomas A. Edison, which position he held until 1894. In 1893 he was in addition consulting electrician to the Edison General Electric Co. (now the General Electric Co. of New York).

In 1902 Kennelly was appointed professor of electrical engineering at Harvard University and occupied that chair until his retirement as emeritus professor in 1930. During the years 1913–24 he was professor of electrical engineering at the Massachusetts Institute of Technology, being appointed emeritus professor of that Institute also.

From 1894 until 1902 he was in partnership with E. J. Houston, the firm acting as consulting engineers. He was president of several societies, including the American Institute of Electrical Engineers, and the Illuminating Engineering Society during the early years of that organization. He was also president of the Metric Association.

In the international field, Kennelly's services have been of the highest distinction. He was a United States delegate to the Electrical Congresses of 1900, of 1904, where he carried out the onerous duties of general secretary, and in 1932. He was also delegate to the International Radio Conferences in Paris in 1921 and in Washington in 1927, where allocations of radio transmission frequencies were made to the nations of the world. He was a member of the International Committee of Weights and Measures and attended the meeting at Sèvres in 1933. Durin the year 1921–22 he represented seven co-operatin American universities as first 'exchange' professor i engineering and applied science at several French universities. In 1931 he gave a series of lectures i Japan under the Iwadare Foundation. He ha published many books and is the author of more than 350 papers, many of which were presented befor scientific organizations at home and abroad. He wa unflagging in his attendance at committee meeting and was the chairman of the committee on electrica definitions which has done very useful work.

In 1900, Kennelly was very interested in the progress made by Lodge, Fleming and Marconi in wireless transmission. When many mathematicians were proving that the transmission of wireless waves round the curvature of the earth was a physical impossibility, Marconi transmitted waves from Poldhu in Cornwall to Newfoundland. Kennelly, on March 15, 1902, was led to believe that the wireless waves were reflected by some kind of cloud producing a 'mirror' effect which bent the waves round the earth's surface. Kennelly and Heaviside both thought of a reflecting layer of ionized gas which could reflect the rays. This layer has since been called the Kennelly-Heaviside layer.

In 1924 Appleton demonstrated the real existence of a 'mirror' layer. The regular variation in reception, as the wave-length was changed, proved its existence, and later experiments proved that there was more than one reflecting layer in the atmosphere.

One of the most useful mathematical methods popularized by Kennelly was the use of Argand's method of using complex numbers to aid computers, thus saving much arithmetical labour. In April 1893 in a paper published by the A.I.E.E. under the title "Impedance", he applied complex qualities to technology and to the extension of Ohm's law to alternating current theory. He calls the inductance multiplied by 2π times the frequency, the "inductance speed". The impedance is therefore the geometrical or vector sum of the resistance and the inductance speed. We thus find what is often called the Ohm's law for alternating currents, which simplifies the everyday theory of the practical electrician. The impedance of inductive coils in series is readily determined, and when two or more inductive coils are in parallel the component currents are easily found. This can be done both graphically and algebraically. In the latter case, the solutions are expressed in terms of hyperbolic functions, which in the absence of tables are sometimes very laborious to compute. He therefore edited charts and tables of hyperbolic functions to several decimal places, for which there has been a great demand by practical electricians all over the world, as by the use of the tables and charts there is a great saving in the time taken by computers, and the accuracy required nowadays is much greater than that required thirty years ago. They are much used in long-distance telegraphy and telephony.

Kennelly was very popular with his old students, who used to go from all parts of the world to study under him. I remember that before the Great War

I sent one of my students who was a graduate of London to do research under Kennelly. He often wrote saying how kind the professor was to him, having him to his house every week and going for a picnic into the country on holidays. Unfortunately, war broke out and he returned to join the army and paid the great sacrifice. I communicated the sad news to Prof. Kennelly and received a long letter back telling how popular the student was at Harvard, and how he took a leading part in all their sports and how they would ever remember him. They placed a memorial at Harvard.

By all who knew him, Kennelly will be sadly missed, but it is pleasant to remember that to him it was given to have a long and useful life spent in the service of his fellow men.

A. RUSSELL.

WE regret to announce the following deaths:

Prof. J. Grinnell, professor of zoology and director of the Museum of Vertebrate Zoology in the University of California, on May 29, aged sixty-two years.

Mr. F. W. Jones, O.B.E., known for his work on the chemistry of explosives, on June 24, aged seventy-two years.

Dr. Witmer Stone, emeritus director of the Academy of Natural Sciences of Philadelphia, on May 23, aged seventy-two years.

Prof. A. E. Wells, professor of metallurgy in Harvard University during 1926–31, on May 24, aged fifty-five years.

Prof. J. E. Woodman, emeritus professor of geology, in New York University, on May 19, aged sixty-five years.

NEWS AND VIEWS

Prof. V. Gordon Childe

PROF. V. GORDON CHILDE, whose election as an honorary member of the Prehistoric Society of Switzerland in recognition of his services to prehistoric archæology is announced, has been professor of prehistoric archæology in the University of Edinburgh since 1927. This chair, which he is the first to hold, was founded in memory of the late Lord Abercromby, himself distinguished as a pioneer in study of the Bronze Age in Europe. Prof. Childe, who is an Australian by birth, has travelled extensively in Greece, the Balkans, central Europe, and the East. His early visits to eastern European sites strongly influenced the line of his development in archæological thought, leading him to appreciate, more fully, perhaps, than had been done by archæologists previously, the importance of the Danube Valley and adjacent regions as a key position in the study of European prehistory. During his tenure of the chair in Edinburgh, Prof. Childe has not only been active in promoting general interest in archæological studies in Scotland, but he has also taken a leading part in the organization of field research on Scottish sites. Of his own work in the field, the excavation of the stone age village settlement of Skara Brae in the Orkneys ranks as the most remarkable revelation of a complete prehistoric cultural unit which has yet been made in Northern Europe. His contributions to the literature of prehistoric archæology are all remarkable for their grasp of detail, combined with an unusual breadth of view in tracing the general trends of development, as well as for insight into the interplay of the underlying forces, especially such as belong to the field of prehistoric economics.

Newton's Correspondence

THE Royal Society has formed a committee for the purpose of collecting and publishing the whole of the correspondence of Sir Isaac Newton. It is hoped that a substantial part of the work will be completed and that some of the volumes will be issued by the time of the celebration of the tercentenary of Newton's birth in 1942. The members of the committee are as follows: Sir Charles Sherrington (chairman), Prof. E. N. da C. Andrade, Prof. G. N. Clark, Sir William Dampier, Sir Arthur Eddington, Sir Thomas Heath, Dr. H. Spencer Jones, the Librarian of Trinity College (Mr. Adams) and Prof. H. C. Plummer. The Council invited Prof. Plummer to be the editor of the correspondence and he has accepted this great responsibility. It is hoped to obtain the co-operation of all librarians in the various libraries of America and of Europe, and notifications of any original letters appertaining to Newton in their collections should be sent to the Assistant Secretary of the Royal Society, Burlington House, London, W.1.

Malaya and India: Early Cultural Relations

CONFIRMATION of a conclusion, which ran counter to generally accepted opinion, as to the archæological possibilities of Malaya in the study of early cultural development in south-eastern Asia, has been afforded by the results of a fourteen months' archæological investigation undertaken by the Greater India Research Committee during 1937–38. Excavations were carried out in Kedah, Perak and Johore under the field direction of Dr. H. G. Quaritch Wales, by whom the results have been described recently (*Illustrated London News*, June 24), and with the financial assistance of the Governments of the States interested. The most extensive and important of the excavations were in Kedah, some thirty sites, ranging in date from the fourth to the thirteenth century of our era, being thoroughly examined. The earliest remains are scattered and do not suggest any very large settlement before the sixth century. The oldest site found was on an isolated hill on the Sala River, some twenty miles north of Kedah Peak. Here was found the massive laterite basement of a *stupa* and a small stone inscribed with a Buddhist formula in a South Indian script, not later than the second half of the fourth century. Another *stupa* site to the south on the Bujang stream produced a sun-dried clay tablet, inscribed with three stanzas of a Mahayana text in Sanskrit, which previously was known only in Chinese. This antedates previous evidence from Sumatra of the introduction of Mahayana Buddhism into Indonesia by more than a hundred years.

EXCAVATION of mounds on the site of the ancient city of Lankasuka revealed remains of Shiva temples and established the Pallava affinities of the art of the colonists in the seventh and eighth centuries, while foundation deposits from temples excavated on Kedah peak consisted of caskets, which, though undoubtedly Indian in character, are of a type unknown in India and are explicable only by reference to Java. The ruined state of the temple buildings made it possible to excavate the foundations more thoroughly than is usually possible, with the result that much valuable information as to dating and cultural relations with southern India was obtained from this source. Especially noteworthy is evidence of a revival of Hinduism in the eleventh to fourteenth centuries. These results, as well as those of earlier expeditions of the Greater India Research Committee, for which Dr. Wales has been responsible, suggest that the criticisms directed against the projected exhibition of the art of Greater India (see NATURE, July 1, p. 20) are outweighed by the advantages which will accrue to Indian cultural studies from the enhanced knowledge and interest in the art and archæology of Greater India which such an exhibition must arouse. This should result in stimulating further exploration and research. By tracing and exemplifying local developments of Buddhistic and Hindu art, the exhibition should in itself supply the unifying link, of which the absence has been imputed as one of the gravest defects of the proposal.

Civil Defence

THE second Bulletin of the Air Raid Defence League gives an outline of civil defence in which the general framework is reviewed as a whole, so that the various technical, social and economic problems fall into their proper prospective in the defence of the whole living organism of a nation in a war zone. After discussing the nature and object of air attack and the policies which might be used by the attacker, the Bulletin concludes that evacuation of the congested target areas is the most radical strategic move and is called for on a much wider scale than is at present announced by the Government. It is urged that all who can should be evacuated and only special classes should stay. Careful planning of evacuation and action before war is in being could vastly reduce the dislocation caused by evacuation. A priority scheme, however, is required as the basis of defence measures in which the proportionate risk has been roughly calculated on scientific principles. Bomb-proof accessible shelter both for work and for rest is advocated for those whose duty it will be to remain at work in the congested target areas and for the protection of those engaged in running vital services such as telephones or first aid. For less congested and vulnerable areas shallow shelters of the Anderson or other types or strengthened basements must be provided, and small communal shelters or strengthened basements for large blocks of flats or offices are necessary.

THE apathy of local authorities and the lack of staff for effective training are criticized as the chief hindrances to the effective utilization of volunteers in national service. The Bulletin then urges the importance of policy being designed to make the economic system of Great Britain strategically less vulnerable. The Government should give a clear lead to industry to organize itself to meet war conditions and to undertake the preparation of suitable alternative premises and services of supply and to provide pools of reserve plant. Similarly the maintenance of food supply is of paramount importance. Reserve stocks of food must be accumulated and protected. Facilities for handling and storing food and essential commodities at ports at present little used but likely to be important in time of war in view of their comparative safety should be improved. Much of our present storage is in highly vulnerable positions; so production of food should be greatly increased. Special stress is also laid upon the mobilization of science, the full resources of which are insufficiently utilized by the Government. Among subjects for urgent team research methods are food and storage, optical instruments, special drugs and shelter problems. The importance of full publicity is emphasized and establishment of a Ministry of Information is recommended.

Earthquakes in California

ON the morning of June 23, an earthquake of considerable intensity was felt along the whole of the coast of Southern California. It was particularly severe at Hollister and Salina, where it was said to be the worst since 1906, though no material damage was done. California is particularly prone to local earthquakes and tremors, and a glance at the geomorphic map prepared by the Earthquake Investigation Commission shows that considerable movement has taken place from time to time along the great fault systems which chiefly run parallel with the coast line. In this particular instance it is difficult to state exactly where the epicentre may have been, but it is possible that slipping may have taken place along the San Andreas Fault which runs practically along the whole length of the affected area and lies approximately midway between Hollister and Salina. A second shock was felt at Pasadena and San Diego in the early afternoon of the same day. This probably had its epicentre in the mountainous region of Nevada; it was sufficiently intense to have caused considerable damage had it occurred in a densely populated region. California has several seismological observatories, so that thorough investigations will no doubt be made of these shocks. A descriptive catalogue of earthquakes of the Pacific coast of the United States from 1769 to 1928 was published in January 1939 by the Seismological Society of America. The recorded shocks for California occupy 231 pages whilst those for the remainder of the coast occupy 44 pages.

Soviet Census

More complete figures relating to the census of the Soviet population taken on January 17, 1939, have been issued by the State Planning Commission of the U.S.S.R. The figures cover the entire population of the Union with the exception of the far north, where the census will be taken in the latter half of this year. The figures issued reveal that on January 17 last, the population of the Soviet Union numbered 170,467,186, including 81,664,981 males and 88,802,205 females. As compared with the census of 1926, the Soviet population has increased by 23,439,271 or by 15·9 per cent, the urban population being 55,909,908 or 32·8 per cent of the total, as against 26,314,114 in 1926, or 17·9 per cent of the total. Owing to a typographical error in the note which appeared in Nature of June 3 (p. 936), relating to preliminary figures of the Soviet census, it was stated that the entire population had more than doubled. This should have read "the urban population has more than doubled". The average annual increase of population in the U.S.S.R. during the period 1926–39 was 1·23 per cent. The increase in the birth-rate is illustrated by figures relating to some of the big towns of the Union. In 1938 the average number of births per thousand of population in Moscow was 28·5, Leningrad 27·4, Kiev 27·4, Kharkov 27·7, Baku 33·9. There are 174 towns in the U.S.S.R. with populations of more than 50,000; 82 have populations of more than 100,000 and eleven have populations of more than half a million. The population of Moscow has increased from 2,029,425 in 1926 to 4,137,018 in 1939, or by 103·9 per cent, and that of Leningrad from 1,690,065 in 1926 to 3,191,304 in 1939, or by 88·8 per cent. Four towns are included in the 1939 census which did not figure on the geographical maps in 1926, namely, Karaganda which now has a population of 165,937, Magnitogorsk with a population of 145,870, Stalinogorsk with a population of 76,207, and Komsomolsk-on-Amur with a population of 70,746. During the period 1926–39, 1,536 new urban centres, 213 of which have been constituted as towns, have sprung up on the territory of the Soviet Union.

Pulkovo Observatory

The chief observatory in the U.S.S.R., situated at Pulkovo, a few miles outside Leningrad, celebrates the hundredth anniversary of its foundation this year. To-day a number of buildings devoted to astronomy and related sciences surround the original central edifice, with its circular hall through the middle of which runs the Pulkovo meridian. This hall is now used as the observatory's museum, and it contains some extremely interesting exhibits, including a working model of the solar system, made by an unknown craftsman 150 years ago. Not only do the earth and planets revolve around the sun in this model, but also the glass shade which covers it is utilized for representation of the stars and constellations. The library, situated in a gallery around the main dome, contains some very valuable unique works, including Kepler manuscripts. The Pulkovo Fundamental Catalogues of Stars are widely known for the accuracy of the observations entered in them. Needless to say, the observatory is also rich in astronomical photographs and similar research materials. At the time of its foundation the refractor installed in the observatory, one with a lens of fifteen inches diameter, was the largest in the world. It was added to in 1885 by the installation of another refractor with a thirty-inch lens.

Positive Eugenic Policy

In his Galton Lecture, Dr. C. G. Darwin discussed a positive eugenic policy (*Eugenical News*, 31, No. 1). He pointed out that a eugenic policy could only exist under conditions of civilization. In centuries up to the nineteenth, populations were stationary or increased but slowly. Then wages began to rise or the price of wheat went down, and with it the mortality rates in infancy and adulthood. It was no longer essential to have a certain level of intelligence in order to stay alive. Natural selection ceases to operate in civilization, and the things on which surpluses shall be spent are determined by advertisements. The relative absence of natural selection inevitably leads to degeneration unless eugenic selection can take its place. As regards negative eugenics, the propagation of mental weakness is much more serious than the transmission of a bodily weakness with a high intellect. As regards positive eugenics, we need not wait for full knowledge of the human genetic constitution, to construct human beings as an engineer constructs a bridge. Quite enough is already known with reasonable probability for immediate eugenic action. Bohr's principle of complementarity, implying a mutual effect of subject and object, comes in here. The need is urgent for a simple national eugenic policy which will induce the better endowed to have larger families, and history will not spare us if we do not set to work at once to carry it out.

Forestry at Oxford

A statute amending the regulations for the School of Forestry at Oxford has recently been approved and comes immediately into force. Hitherto the normal avenue to the final examination has been a special preliminary examination of a comparatively simple nature that could be taken by the student, if he wished, before he came into residence. Now the prior qualifications required of candidates for the final examination are so much higher that the School becomes, in part at least, a post-graduate one. Candidates are now required to have obtained honours in the new Science Moderations examination or in some final school or to be graduates of another university and they must have passed approved examinations in botany, geology, physics and chemistry if these have not been taken in the degree courses. The reason for this change, and the concurrent change in the curriculum of the School, is found in the requirements of the forest services and the development of forestry in the Empire. It has been decided also that after August of this year the Imperial Forestry Institute, established in 1924 and controlled by a director other than the professor of forestry since 1936, is to be joined to the professor's department as a self-contained unit under the immediate charge of the professor. Between 1920 and 1938, 324 men have been trained in the School of Forestry, 258 of whom have passed into the various forest services. During the fifteen years of the independent existence of the Institute, there have been 350 students in attendance.

International Bibliography of Agricultural Economics

THE International Institute of Agriculture at Rome has just issued the first number of a new quarterly publication—the *International Bibliography of Agricultural Economics*—compiled under the technical direction of the librarian, Dr. S. von Frauendorfer. The need for a bibliography of this nature was realized in 1932, and since 1933 twelve publications on these lines have appeared in the journal *Berichte über Landwirtschaft* (Parey, Berlin). The thirteenth issue, giving the literature up to June 1, 1938, will be found in the *Berichte* as usual, but subsequent publications are given in the new volume. The *International Bibliography of Agricultural Economics* covers the economic and social aspects of agriculture, such as agricultural economics, agricultural policy, settlement, credit, co-operation, insurance, marketing, prices, statistics, farm organization and management, valuation, labour, accounting, rural sociology, agricultural history and geography, legislation and education and all other agricultural problems, in so far as they are considered from the economic and social point of view. Only publications of purely technical character are excluded. Titles of all publications, whether books, bulletins, pamphlets or articles in periodicals, are indicated, including all bibliographical details required for proper identification. All languages receive equal treatment, and titles in the less known languages are provided with a translation. The bibliography, which is the only one covering systematically the world literature on agricultural economics, is carefully classified by subjects. An author index will be supplied at the end of each volume. The annual subscription, postage included, is 6*s*. 6*d*.

Seale-Hayne Agricultural College

THE criticism is frequently made that the investigations of colleges and research institutes are not reported to the farmer in a form that can be easily understood. To meet this need, and at the same time to make the work of the College more widely known, Seale-Hayne Agricultural College, Newton Abbot, Devon, is issuing an annual in which it is hoped to deal with a wide variety of subjects in a manner likely to prove of real value to the practical man. The first number has just been published. It contains articles on the chemical composition of broccoli, potato eelworm, varieties of winter oat, and on the animal husbandry side, efficiency factors in the production of bacon pigs, milk production costs and the building up of a tuberculosis-free dairy herd. A list of investigations in progress at the College and of pamphlets already published is appended. Though of particular value to farmers and growers in the south-west of England, the volume will no doubt be also of interest to agriculturists in other districts.

The John Innes Horticultural Institution

THE John Innes Horticultural Institution is unique in Great Britain in combining research in genetics, cytology and biochemistry with pomology and horticulture. The twenty-ninth annual report contains the results of the investigations during the year 1937–38. Two interesting discoveries in cytology were that the chiasmata in the megasporocytes were less randomly distributed than in the microsporocytes of *Lilium testaceum* and that the centromere could divide sometimes transversely as well as longitudinally. The genetical analysis of *Tropaeolum*, *Streptocarpus*, *Verbena*, *Zea*, *Lotus* and *Primula sinensis* is proceeding. There are two linkage groups of most of the identified colour genes in *Streptocarpus*; both groups exhibit tight linkage between the genes. 16 genes of *Verbena* may be assorted into five linkage groups. The investigation of *Rubus* species has shown that different varieties, usually polyploid, may be (1) sexual, (2) apomictic, or (3) partly sexual and partly apomictic in reproduction. Even the apomictic varieties can segregate, thus indicating that the first division of meiosis occurs in these forms. The Biochemistry Department has been investigating several interesting new plant pigments such as dunnione in *Streptocarpus Dunnii* and anthocyanins from ferns and unusual sap-soluble substances in *Celosia*. The training of gardeners and the investigation of suitable soil composts again met with success and good use was made of the provision of research facilities for visitors.

Bibliography of Seismology

WE have recently received vol. 12, No. 19 (July, August and September 1938) of the Bibliography of Seismology, published by the Dominion Observatory at Ottawa. This time 117 works are listed and there are twenty-six collaborators representing 12 countries. It contains references among many notable works to Dr. C. Davison's "Studies on the Periodicity of Earthquakes" and works by Gutenberg and Richter, Lynch, and Bullen all bearing on the problem of the earth's central core. Particularly interesting is the notice of the article on Frank Lloyd Wright from *Readers Digest*, directing attention to the importance of the design of buildings in earthquake-troubled countries. Wright designed the Imperial Hotel in Tokyo to withstand earthquake shocks, and it has done so.

World Bibliography of Bibliographies

THE need for the making of bibliographies arises om the multiplicity of books, the excessive pro-uction of which was a matter for complaint before e invention of printing. Bibliographies, or lists books, existed before the Christian epoch. Not ng after the introduction of printing, the recording all books made became impossible and the difficulty came one of keeping track of bibliographies. ventually the ever increasing number of biblio-aphies of bibliographies has justified the publication Mr. Josephson's bibliography of bibliographies of bliographies. To-day the aggregate of existing bliographies is countless. Thanks to the work of e International Federation for Documentation, an creasing number are produced according to a andard system. Such bibliographies can be amal-amated into a single index, where all references to particular topic, collected from a variety of sources different languages, can be found immediately in ne place. The great mass, however, are arranged ccording to a variety of systems, mostly alphabetical, hich make amalgamation impossible. The adoption f individual systems gives rise to the need for a ork by which to ascertain what bibliographies have een compiled on a given subject, and Mr. T. esterman is attempting to meet the need by a "World Bibliography of Bibliographies" to contain bout 24,000 entries of separately published biblio-raphies of all countries on all subjects. In addition o printed books, it will cover every sort of written atter as well as the subject classes of Patent Office bridgements from 1617 until 1930. It is promised n two volumes, the first on October 1, 1939 and the econd early in 1940. Orders should be sent to Mr. T. Besterman, 98 Heath Street, London, N.W.3.

International Federation for Documentation

THE fifteenth International Conference of the International Federation for Documentation, which s being organized by the Swiss Association for Documentation, will be held at Zurich under the residency of Dr. Philipp Etter, president of the Swiss Republic, during August 10–13. The International Federation for Documentation, the seat of which is at The Hague, was founded for the purpose of studying all particulars concerning the publication of new information and of developing means whereby it may be made available as required. At the World Congress on International Bibliography two years ago at Paris, the Federation was adopted unanimously by delegates of more than forty Governments as the international authority in such matters. One of the main objects of the Federation is the great work of promoting the subject-indexing of information, since information that has not been catalogued by subject cannot be found unaided except by accident, by the individual research worker. It can be made available only by systematic and comprehensive indexing. Consequently the Federation endeavours to bring together in direct collaboration all bodies and individuals interested in the mobilization of knowledge.

AMONG the methods adopted by the Federation is the promotion of international conferences. Full conferences are held biennially in different countries: that held last year at Oxford under the patronage of the British Government and the presidency of Sir William Bragg will be remembered by many. In alternate years smaller conferences, restricted to selected topics, are held. The subjects for discussion at the Zurich Conference comprise: (1) the division of work between librarians and documentalists, (2) documentation in connexion with administration, (3) documentation in industry and (4) photographic reproduction methods for documentation purposes. The Conference includes visits and excursions to works and places of interest in the neighbourhood. Everyone concerned with the increase or organization of knowledge should make a point of attending. Special travelling facilities are afforded in connexion with the Swiss National Exhibition. The membership fee is 20 Swiss francs and the papers will be printed in advance and sold at the price of 10 Swiss francs. The address of the secretary is Herr E. Mathys, Chemins de Fer, Bern, Switzerland.

Zoology in China

IT is gratifying to note that the *Bulletin of the Fan Memorial Institute of Biology* of Peiping (Pekin), now in its eighth volume, has been able to continue publication notwithstanding the disturbed condition of internal affairs prevailing in China. The last issue to hand of the Zoological Series (No. 3, July–August 1938) contains eight articles, all of which are written by Chinese zoologists. The most extensive are S. C. Yu's studies on Chinese Crustacea of the group Caridina and those by Messrs. Hsu and Chow on helminths of the human intestine. The articles are all written in English and have Chinese summaries.

Royal Commission Science Research Scholarships

THE Science Scholarships Committee of the Royal Commission for the Exhibition of 1851 announces the following appointments for 1939. *Senior Studentships:* On the recommendation of the University of Cambridge: Mr. S. Devons, for research in nuclear physics at the University of Cambridge; Dr. E. F. Gale, for research in biochemistry at the University of Cambridge; Mr. F. Hoyle, for research in theoretical physics at the University of Cambridge; Dr. W. J. C. Orr, for research in physical chemistry at the University of Cambridge. On the recommendation of the University of Oxford: Dr. F. C. Frank, for research in physical chemistry at the University of Cambridge. *Overseas Scholarships:* On the recommendation of McGill University, Montreal: Dr. H. B. Newcombe, for research in genetics and cytology at the John Innes Horticultural Institution, Merton, and the California Institute of Technology, Pasadena; Dr. R. L. McIntosh, for research in physical chemistry at the University of Cambridge. On the recommendation of the University of Toronto: Dr. H. E. Johns, for research in physics at the University of Cambridge. On the recommendation of the University of Sydney: Miss R. H. Harradence, for research in organic chemistry at the University of Oxford; J. W. Cornforth, for research in organic chemistry at the University of Oxford. On the recommendation of the University of New Zealand: A. J. C. Nicholson, for research in physical chemistry at the University of Cambridge. On the recommendation of the University of Cape Town: C. B. Coetzee, for research in geology at the University of Cambridge. On the recommendation of the University of Dublin: B. P. Beirne, for research in entomology at the British Museum (Natural History), London. On the recommendation of Benares Hindu University: Dr. P. B. Mathur, for research in plant physiology at the University of Cambridge.

Announcements

PROF. L. J. HENDERSON, Lawrence professor of chemistry at Harvard University, who is distinguished for his investigations on the physico-chemical structure and organization of the body, has been invited by the Royal Society to deliver the next Pilgrim Trust Lecture which is to be given in London. Prof. Henderson has accepted the invitation. In referring to the Pilgrim Trust Lectures in NATURE of July 1, p. 15, it was incorrectly stated that the selection of Sir William Bragg to deliver the second lecture of the series had been in the hands of the Royal Society; the Royal Society invites American men of science to lecture in England under the scheme, while the National Academy of Sciences invites a representative of science in Great Britain to lecture in the United States.

AT a meeting held in Paris on June 30, the president of the Société des Ingénieurs Civils de France, M. Raymond Berr, presented the Gold Medal of the Société (Prix Annuel) to Mr. W. T. Halcrow, for his paper entitled "Tapping a Lake at 32 metres below the Surface" read before the Société in Paris on May 27, 1938. This is the first occasion on which the premier prize medal of the Société has been presented to a British subject since its award was instituted in 1861. Mr. Halcrow, who is the president of the British Section of the Société des Ingénieurs Civils, described in his paper the Ben Nevis tunnel through which water from Loch Treig is delivered to the British Aluminium Company's power station at Fort William.

THE following have been elected honorary members of the Royal Society of Edinburgh: Harvey (Williams) Cushing, emeritus professor of neurology, Yale School of Medicine, Newhaven, Conn.; Otto Loewi, lately professor of pharmacology, University of Graz; Bernard Lyot, of the Observatory, Meudon.

THE following have been elected to the Physical Mathematical Class of the Prussian Academy of Sciences: Prof. A. Butenandt, director of the Kaiser-Wilhelm Institut für Biochemie in Berlin; Prof. K. Meyer, director of the Institut für Ackerbau und Landbaupolitik, Berlin; Prof. A. Ludin, professor of hydraulic and agricultural hydraulic engineering, Berlin; Dr. F. Seewald, director of the Deutsche Versuchsanstalt für Luftfahrt, in Berli and Prof. J. Bartels, professor of geophysic Berlin.

DAME HELEN GWYNNE-VAUGHAN, professor botany in Birkbeck College, London, has bee appointed director of the Auxiliary Territorial Se vice, Army Branch, with rank of Chief Controller, from July 3.

THE Council of the Institution of Civil Enginee has approved of the formation of a Railway Enginee ing Section which will include within its scope a matters appertaining to the study of railway enginee ing relating to planning, construction, maintenanc and research, and including structures, rolling-stoc and equipment, the matters akin thereto.

THE Council of the Royal Meteorological Societ has awarded the Howard Prize (an aneroid barometer given annually for the best essay on a selecte meteorological subject, to Cadet V. A. McMillan, o H.M.S. *Conway* School Ship. Cadet C. D. Thorpe also of H.M.S. *Conway*, was placed second in th competition. The subject of the essays was "Th Barometer and its Use in Meteorology"

THE International Society for the Investigation o Biorhythms will hold its second conference a Utrecht, Holland, on August 25–26, under th presidency of Dr. E. Forsgren. Dr. H. Holmgren of the Karolinske Institutet, Stockholm, is th secretary. Further information can be obtaine from Dr. Frits Gerritzen, Lunteren, Holland.

THE eleventh Congress of the International Unio against Tuberculosis will be held in Berlin on September 16–20 under the presidency of Dr. Ott Walter. The main subjects for discussion will be the problem of the virulence of the tubercle bacillus; the value of systematic examinations for the detection of tuberculosis in subjects more than fifteen years of age; and the rehabilitation of the tuberculous. Further information can be obtained from the National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, W.C.1.

A JOINT meeting of the Royal Meteorological Society and the American Meteorological Society will be held in Toronto on the occasion of the meeting of the International Union of Geodesy and Geophysics in Washington early in September. The joint meeting will be held during August 28–29, and is being organized by Mr. J. Patterson, controller of the Canadian Meteorological Service. Seminars on radiation and on extra-tropical cyclones will be held. It is also hoped that a Canadian branch of the royal Meteorological Society may be inaugurated at this meeting. Further information can be obtained from Mr. J. Patterson, Meteorological Office, 315 Bloor Street West, Toronto, Ontario, or from the Assistant Secretary of the Royal Meteorological Society, 49 Cromwell Road, South Kensington, London, S.W.7.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 79.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Glutamic Acid of Tumour Proteins

IN a recent paper, Kögl and Erxleben[1] record some interesting observations which suggest that the proteins of malignant tissues are partially 'racemized'. From several normal tissues they were able to isolate, after short acid hydrolysis, relatively good yields of the usual $l(+)$ glutamic acid, showing, in 9 per cent hydrochloric acid, the normal rotation of $[\alpha]_D$ +31·6°, whereas the products isolated from an ovarian tumour, an ovarian carcinoma and from two different mammary carcinomas showed rotations of $[\alpha]_D$ + 21·8°, + 4·6°, + 11·6° and + 16·1°, suggesting that they contained 15·6, 42·7, 31·7 and 24·6 per cent respectively of $d(-)$ glutamic acid. The importance of these findings needs no emphasis, and confirmation in other laboratories is clearly desirable.

During the past two years, an extensive research has been in progress at the Imperial College on the dicarboxylic acid content of various standard proteins. This has given the workers here considerable experience in the rapid isolation of glutamic acid hydrochloride from protein hydrolysates, and opportunity has accordingly been taken of investigating some tumour proteins. The method of analysis employed in these particular cases was essentially that of Foreman[2], modified so that the precipitation of the insoluble calcium salts (from an aqueous volume corresponding to 1 gm. total nitrogen per 60 ml.) with 9 volumes of (95 per cent) ethyl alcohol, was repeated a second time under the same conditions. Provided that the protein had been hydrolysed for twenty hours with 20 per cent hydrochloric acid, previous experience had shown that the fraction recovered from the insoluble calcium salts prepared in this way had all its nitrogen in the amino form and consisted essentially of dicarboxylic acids. Furthermore, on acidifying the solution with hydrochloric acid and concentrating *in vacuo*, the major part of the glutamic acid separated at once as its hydrochloride (cf. Sharp[3]). Since in the case of the tumour proteins the object was to prepare this hydrochloride in reasonable amount for further characterization, no attempt has yet been made to increase the yield by appropriate treatment of the mother liquors. Brief details of four analyses are as follows.

(1) *Crocker Sarcoma* 180. 206 gm. of Crocker sarcomata, from 46 mice, were minced and treated twice with 824 ml. of acetone. The insoluble matter, after drying at 110°, weighed 30 gm. 24·5 gm. of this material were hydrolysed for seven hours with 130 ml. of concentrated hydrochloric acid. The dicarboxylic acid fraction contained only 90·8 per cent of its nitrogen in the amino form, and on concentration in the presence of excess hydrochloric acid 2·43 gm. of material separated. On recrystallization from concentrated hydrochloric acid (charcoal) this gave 1·83 gm. of glutamic acid hydrochloride (found: N = 7·61 per cent; $[\alpha]_D$, in 9 per cent HCl = + 31·4°).

(2) *Carcinoma of Bronchus.* (*a*) A solid trabecular polygonal-celled carcinoma of right bronchus from a man (A.T., aged 59 years). There were metastases in the left lung, spleen, adventitia of aorta and brain. Tumour tissue (600 gm.) from the primary tumour was finely minced and extracted with six volumes of 0·6 per cent sodium chloride, the mixture being shaken at a temperature not exceeding 5° for twenty-four hours. The extract, separated by centrifuging and filtering, was treated with four volumes of alcohol and the precipitate separated, washed and dried at 110° to give 26 gm. of dry material. 14·4 gm. of this were hydrolysed for twenty hours with 20 per cent hydrochloric acid (10 volumes). The dicarboxylic acid fraction, all the nitrogen of which was in the amino form, gave 1·57 gm of insoluble hydrochlorides. On recrystallization 1·2 gm. of glutamic acid hydrochloride were obtained (found: N = 7·64 per cent; $[\alpha]_D$, in 9 per cent HCl = + 31·7°).

(*b*) The material insoluble in the 0·6 per cent sodium chloride solution was treated with 80 per cent alcohol and dried at 110°, giving 73 gm. of dry material. 48 gm. of this were hydrolysed with 20 per cent hydrochloric acid for twenty-four hours. The insoluble hydrochlorides from the dicarboxylic acid fraction gave, on recrystallization from concentrated hydrochloric acid (charcoal), 3·21 gm. of glutamic acid hydrochloride (found: N = 7·65 per cent; $[\alpha]_D$, in 9 per cent HCl = + 31·5°).

(3) *Extension in Neck from Carcinoma of Bronchiole.* An oat-cell carcinoma arising from a bronchiole in the apex of the left lung of a man (N.H., aged 56 years) had extended along the lymphatics into the neck and had invaded the jugular vein, brachial plexus, cervical sympathetic and vertebral bodies. Material (266 gm.) from the growth in the neck was minced and extracted with 0·6 per cent sodium chloride. The extract, on precipitation with alcohol and drying as in 2(*a*), gave 9·1 gm. of dry protein, while the insoluble residue, treated as in 2(*b*), gave 16 gm. of dry material. The two products were mixed and 17·6 gm. were hydrolysed with concentrated hydrochloric acid for seven hours. The insoluble hydrochlorides (1·525 gm.), on recrystallization from 20 per cent hydrochloric acid, gave 1·2 gm. of glutamic acid hydrochloride (found: N = 7·64 per cent; $[\alpha]_D$, in 9 per cent HCl = + 31·2°).

These preliminary results are not in agreement with those of Kögl and Erxleben, and show the need for a more extended investigation. Of course, no claim is made that the material which was used in these analyses was composed wholly of cancer cells; thus tumour (3) above contained a large proportion of fibrous tissue. The difficulty of obtaining large quantities of malignant cells free from other materials is familiar to all engaged in cancer research. But there is no doubt that all three tumours contained enough cancer tissue to show the character in question, if this were present.

We are indebted to Dr. W. G. Barnard, pathologist in charge of the Central Histological Laboratory of the London County Council, and to Dr. L. M. Hawksley, pathologist of the Royal Cancer Hospital, for supplying and identifying the human malignant tissues used.

Interaction between the Phosphatides of the Plasma and the Corpuscles

PLASMA and corpuscles both contain appreciable amounts of phosphatides, that is, about 80 mgm. per 100 c.c. of plasma and 200 mgm. per 100 c.c. corpuscles. To determine if any exchange takes place between the phosphatides of the plasma and those of the corpuscles we carried out the following experiment.

Labelled sodium phosphate was administered to rabbits and hens. Labelled phosphatides, formed in the liver and to a minor extent in other organs, penetrate partly in the course of the following 24 hours into the plasma. The plasma thus obtained, containing labelled phosphatides, was shaken at 37° under the usual conditions with corpuscles from another rabbit. They were then separated by centrifuging, the corpuscles washed with non-active plasma, and the specific activity (activity per mgm. phosphorus) of the phosphatides extracted from both the corpuscles and the plasma was determined. The results are seen in Table 1, while results obtained in experiments *in vivo* are recorded in Table 2. The results show that, while some of the corpuscle phosphatides are replaced at a remarkable rate by plasma phosphatides, the greater part of the phosphatide molecules present in the corpuscles do not exchange with those of the plasma. Even after the lapse of a week, as experiments carried out on human subjects show, more than one half of the corpuscl phosphatides remains unchanged[1]. In considering thi result we must take into account that in the cours of a week an appreciable number of corpuscles wil have been replaced by new ones which necessaril contain labelled phosphatides, since they are forme in an organism containing such molecules. A possibl explanation of the results obtained is that the phosphatide molecules present in the outer part of the cel membrane are readily exchangeable with the impinging molecules present in the plasma, while the constituents of deeper layers of the corpuscle membrane are not accessible. Most of the phosphatides present in the corpuscles are located in the membrane.

TABLE 1.

Extent of equipartition of labelled phosphatides originally present in the plasma between the phosphatides of the corpuscles and the plasma in experiments *in vitro*.
(Plasma containing labelled phosphatides shaken with corpuscles of another rabbit.)

Animal	Time in hours	Extent of equipartition (percentage)
Rabbit	0·5	1·8
	1·5	3·6
	3·0	4·0
	4·5	5·0
Hen	1·5	1·5
	2·0	2·0
	3·0	1·5

TABLE 2.

Extent of equipartition of labelled phosphatides originally present in the plasma between the phosphatides of the corpuscles and of the plasma of rabbits in experiments *in vivo*.

Time in hours	Extent of equipartition (percentage)
24	16
24	18
24	17
25	16
42	34

In previous work[2], we have shown that almost all the acid soluble phosphorus compounds present in the corpuscles are resynthesized at a very appreciable rate, and that the corpuscles at the end of their lifetime do not contain any significant amount of those molecules of acid-soluble phosphorus compounds which were present in the corpuscles at the time of their formation. The phosphatide molecules present in the corpuscles show a very different behaviour; they are not resynthesized inside the corpuscles to an appreciable extent (we find in experiments *in vitro* that in the course of 3½ hours 1 per cent of the phosphatides present in the corpuscles got labelled); however, a part of them exchanges with phosphatide molecules present in the plasma. The majority of the phosphatide molecules present in the corpuscles remains, however, unchanged during the lifetime of the latter.

The above considerations apply to the average phosphatide molecules. We are engaged in the study of the behaviour of different types of phosphatides.

Activity of β-Alanine in Stimulating Growth of Young Rats on a Diet Deficient in 'Filtrate Factor'

WE have for some time been engaged in a study of the 'filtrate factor'[1] using young rats as test animals and following the technique described by Edgar, El-Sadr and Macrea[2]. The first attempts to purify the material gave evidence that at least two unknown active principles are present in crude preparations of filtrate factor from liver. When the acidified aqueous extract containing the filtrate factor was extracted with ether, a separation was observed. The material from the ether extract gave a definite growth response, which, however, was less pronounced than that obtained with the whole crude filtrate factor, even if large doses were administered. On the other hand, the material from the aqueous layer after complete extraction with ether also produced a definite increase of growth. The combination of both parts gave a greater effect, similar to that obtained with the original material.

The following average increases in weight were observed during the test period of 14 days (average of eight rats in each group). The amounts of supplements correspond to 15 gm. of fresh beef liver. Larger doses had no greater effect.

Negative controls	12 ± 4 gm.
Concentrate of crude filtrate factor	40 ± 9 gm.
Purified ether extract	30 ± 6 gm.
Portion not extractable	25 ± 6 gm.

The component extractable by ether from liver extracts was either absent from yeast extracts or only present in relatively small amounts.

Various known pure compounds were checked for their capacity to replace the ether-soluble portion of the filtrate factor. With β-alanine, positive results were obtained at a level of 0·1 mgm. per day per rat. The results with smaller doses are not yet available. The average increases in weight during the test period of 14 days are given below :

Negative controls	12 ± 4 gm.
1 mgm. β-alanine	18·5 ± 5
0·2 mgm. β-alanine	21·5 ± 6
0·1 mgm. β-alanine	17 ± 3

We have found that rats which have been fed on a diet free from the 'eluate' and 'filtrate factors' until their weight remains stationary, do not give a definite reaction to the addition of β-alanine or acid ether extract of liver, although they show a considerable increase in weight when crude filtrate factor is added to their diet.

While these experiments were being carried out, two remarkable notes appeared dealing with related subjects. T. H. Jukes[3] stated that the "chick-antidermatitis factor"[4] is probably identical with pantothenic acid[5]. This was confirmed by Elvehjem *et al.*[6], who furthermore give proof that pantothenic acid is a derivative of β-alanine containing a hydroxy acid linked to the amino-group. They were able to hydrolyse pantothenic acid into its two components, which were entirely inactive when tested on chicks, but could be linked together again by chemical means to yield a material which again showed the original activity.

The part of the filtrate factor from liver, which is extractable with ether and which stimulates the growth of young rats, contains no free β-alanine. It is quite likely that it is identical with the chick-antidermatitis factor or pantothenic acid. This hypothesis has already been suggested by several investigators, but we could not find any definite proof of it in the literature. The supposition is based chiefly upon the fact that both factors can be obtained from the same sources and by exactly the same methods.

If this supposed identity, as well as our preliminary results, can be confirmed by further experiments, it would indicate that for rats, β-alanine is the essential part of the whole molecule of pantothenic acid, since rats react in a similar way to free β-alanine and to pantothenic acid, and probably to all ordinary esters and acyl derivatives of β-alanine. Chicks and perhaps other animals, under the conditions used in the test for the antidermatitis factor, unlike rats, give no response to free β-alanine but only to the combined form as pantothenic acid. A simple analogy for such behaviour is already known. Mueller *et al.*[7] reported that β-alanine and pantothenic acid both can stimulate the growth of the diphtheria bacillus, and that pantothenic acid can be built up from β-alanine by *C. diphtheriæ*, whilst certain strains of the lactic acid bacteria are apparently unable to effect the synthesis of pantothenic acid from β-alanine.

Addendum. We have meanwhile received an account of work done on similar lines in the Lister Institute, London, and the University of Manchester. Dr. Macrae kindly sent us the manuscript of the letter below. Our results with β-alanine were obtained with 38 rats, using a further 24 animals as negative controls. Experiments are in progress with the object of demonstrating the effect of β-alanine in rats by another method. We fully agree with the British authors that the growth-promoting action of β-alanine on rats is only slight and that it can at most only be regarded as an accessory to the action of the other factors of liver extract.

Vitamin B Requirements of the Rat

Two or three years ago some of us[1], in common with other investigators[2], recognized that the rat required at least four factors of the vitamin B complex—aneurin, riboflavin and two materials, then unidentified, which we named yeast eluate factor and yeast filtrate factor respectively. The yeast eluate factor has since been isolated and identified[3] with vitamin B_6. We have prepared from extracts of liver a fraction replacing the yeast filtrate factor in the diet of the rat[4]; this fraction we believe to contain a single factor, which we have named the liver filtrate factor. We have been for some time engaged on experiments having as their object the purification and eventual isolation of this factor.

This factor is not adsorbed from aqueous solution by fullers' earth nor precipitated from aqueous solution by lead, mercury, silver, quinine or brucine salts, nor by the more common precipitants for bases ; it is, however, precipitated from alcoholic solution by barium hydroxide. From weakly acid solution the factor may be extracted by amyl alcohol, ether or phenol ; after acetylation it is readily extracted with chloroform and the material obtained by hydrolysis of the chloroform-soluble portion is biologically active.

During the past year, further investigation of the essential nutrients contained in aqueous extracts of yeast and liver has led us to the conclusion that the vitamin B complex contains even more than four factors[3] and we have now obtained evidence that this vitamin complex, as required by the rat, has at least six constituents. Although in this brief communication it is impossible to present all the evidence in support of this further complexity, the following experiments give some indications. Young male rats were prepared as for tests for filtrate factor[4] and received, as sources of B vitamins, aneurin, riboflavin and eluate factor (vitamin B_6), the last being given as a nicotinamide-containing concentrate prepared from yeast or liver. When growth had slackened the animals were given various additional supplements as indicated in the following table, all supplements being supplied in optimal amounts. The body-weight of the animals was then observed for periods of two weeks.

Additional supplements given	No. of rats in group	Average total weight increase during 2 weeks (gm.)
None	15	12
Purified liver filtrate factor (soluble in amyl alcohol)	14	43
Acid autoclaved whole extract of liver	4	36
Purified liver filtrate factor + acid autoclaved extract of liver	6	68
Purified liver filtrate factor + the portion of liver extract not extracted by amyl alcohol and not absorbed by fullers' earth	3	64
Whole extract of liver	4	86

Consideration of the growth-rates supported by the various supplements makes it clear that acid-autoclaved whole extract of liver contained an essential factor distinct from liver filtrate factor, and whole liver extract contained at least one further factor. The residue obtained after fullers' earth treatment followed by amyl alcohol extraction of a liver extract also contained a growth factor not present in our purified liver filtrate factor; whether this is the same as that present in the acid-autoclaved extract of liver is undetermined. The rat thus appears to require at least six different factors contained in the vitamin B complex: aneurin, riboflavin, vitamin B_6 and three further substances at present unidentified. We have not been able to demonstrate that nicotinamide is an essential nutrient of the rat but, since the eluate fraction given in our basal diet contained that substance, it is not identical with any one of the three unidentified factors mentioned above.

Although yeast and liver filtrate factor replace each other in the diet of the rat, certain differences have been observed in the behaviour of concentrates of these materials, notably with regard to lability towards acid and alkali and to extraction from acid solution by organic solvents. The possibility that this disparity in behaviour may be due to a fundamental chemical difference between the two factors is at present under investigation.

We have also tested certain substances for vitamin B activity by administration to rats receiving aneurin, riboflavin and eluate fraction; among these β-alanine has been tested at a dosage of 0·5 mgm. and found to give only a very slight growth response. Evidence of a growth effect of β-alanine is recorded in the accompanying communication of Hoffer and Reichstein, whose results we have been privileged to see. From our results, however, we conclude that the growth effect of β-alanine is insignificant and that this substance certainly does not replace our yeast filtrate factor or our liver filtrate factor. In agreement with Robinson *et al.*[7] we found chondroitin sulphuric acid had some growth-promoting action but its effect even in large doses (100 mgm. daily) was slight compared with that of the filtrate factor.

Our experiments have been confined to rats and we are therefore unable to decide the relationship of our factors to pantothenic acid[8], which is probably identical with the chick anti-dermatitis factor[9]. Our liver filtrate factor shows great resemblance in properties to both the chick anti-dermatitis factor and the rat factor termed[10] factor *W*. A decision as to the exact relationship of these factors must await further work.

Pyruvate Oxidation System in Brain

WE have recently reported[1] that the oxidation of pyruvate by finely ground preparations of pigeon's brain is catalysed by fumarate and adenylic acid (or adenosine triphosphate). The effect of fumarate can be obtained in non-dialysed preparations, that of adenylic acid after short dialysis (two hours), when the activity of the system can be fully restored to the value before dialysis. Inorganic phosphate is another component of the system (Table 1). After two hours dialysis the preparations still contain some phosphate (about 0·001 m.) and certainly some fumarate[2], hence the oxygen uptake in the absence of added phosphate or fumarate is slightly higher than in the controls without pyruvate. These facts have now been confirmed with preparations from rabbit's brain.

TABLE 1.

Enzyme from pigeon's brain dialysed for 2 hours. Air, 38°.

Enzyme	Pyruvate (mol × 10^{-6})	Phosphate (mol × 10^{-6})	Adenylic acid (mol × 10^{-6})	Fumarate (mol × 10^{-6})	μl O_2 in 30 min.
1·5	—	50	0·14	5	80
1·5	9·1	50	—	5	88
1·5	9·1	—	0·14	5	102
1·5	9·1	50	0·14	–	150
1·5	9·1	50	0·14	5	350

It is well known that removal of cozymase by dialysis from enzyme systems requires long dialysis periods[3]. Little or no effect of added cozymase is observed after two hours dialysis, but increasing activations are obtained after increasing periods of dialysis (Table 2), thus showing cozymase to be another component of the pyruvate oxidation system.

TABLE 2.

All samples contain dialysed enzyme from pigeon's brain (1·5 ml.) and the following additions (conc. mol × 10^{-3}). Pyruvate (9·1); fumarate (5); phosphate (50). Air, 38°.

Duration of dialysis	μl O_2 in 20 min.			Increase due to cozymase (per cent)
	Enzyme	Enzyme + adenylic acid ($0·14 \times 10^{-3}$ m.)	Enzyme + adenylic acid ($0·14 \times 10^{-3}$ m.) + cozymase ($0·14 \times 10^{-3}$ m.)	
2 hours	71	245	275	12
4 hours	62	189	227	20
6 hours	74	161	232	44
8 hours	46	68	124	82

Although our preparations contain adenylpyrophosphatase, small amounts of easily hydrolysable phosphate (7 min. at 100° in normal hydrochloric acid) appear on incubation with adenylic acid and pyruvate (5 min. at 30°).

Lipmann[4] has recently reported on esterification of inorganic phosphate with adenylic acid, coupled with dehydrogenation of pyruvate, in preparations of lactic acid bacteria. In his system, however, the phosphorylation does not appear to be necessary for the dehydrogenation of pyruvate, which proceeds equally well in the absence of added adenylic acid. Furthermore, dehydrogenation of pyruvate in our brain preparations takes place in the absence of adenylic acid, the ratio oxygen uptake : pyruvate disappearing, fulfilling approximately reaction (1) (Table 3):

$$CH_3.CO.COOH + \tfrac{1}{2}O_2 = CH_3.COOH + CO_2, \quad (1)$$

TABLE 3.

Enzyme from pigeon's brain dialysed for 3 hours (1 5 ml.) with phosphate, fumarate and pyruvate as in Table 2. Air, 28°. 20 mm.

Additions	Extra O_2 uptake due to pyruvate (mols × 10^{-6})	Pyruvate disappeared (mols × 10^{-6})	Ratio O_2/pyruvate	
			Found	Theory (for reaction)
None	0 656	0·873	0·75	(1) 0·5
Adenylic acid ($0·14 \times 10^{-3}$ m.)	5·850	3·960	1·50	(2) 2·5

whereas in the presence of adenylic acid the oxidation of pyruvate proceeds more nearly to completion and the above ratio approaches the theoretical value for reaction (2) (cf. Long[5]):

$$CH_3.CO.COOH + 2\tfrac{1}{2}O_2 = 3CO_2 + 2H_2O \quad . \; . \; . \; (2)$$

It thus appears that the adenylic acid in our system is involved in an oxidation stage beyond that of oxidative decarboxylation and that the further oxidation of pyruvate is connected with a phosphorylation cycle.

The brain dispersions can be resolved by centrifugation into a solid residue which contains the pyruvate dehydrogenase (for reaction (1)) and a solution containing enzymes which, together with the residue, provide for the complete oxidation of pyruvate. The soluble enzymes can be precipitated with acetone or ammonium sulphate without loss of activity.

Thus far our analysis has shown the following substances to be required for the oxidation of pyruvate in brain: (a) cocarboxylase[6]; (b) fumarate; (c) inorganic phosphate; (d) adenylic acid; (e) cozymase. Fumarate can be replaced by malate or oxaloacetate in this brain system but not by citrate; hence a citric acid cycle, such as postulated by Krebs and Johnson[7] for the oxidation of carbohydrate in muscle, appears to take no part in the oxidation of pyruvate in brain.

We are indebted to the Nuffield Trustees and the Rockefeller Foundation for grants in aid of this work.

Bile Production in Tumour-bearing Mice and the Use of Bile in Filtration

THE growth of a mouse sarcoma (Mal. sarcoma) produced originally by a derivative of 1 : 2 : 5 : 6-dibenzanthracene[1] when inoculated into the peritoneum of mice, is accompanied by various changes which resemble those produced by X-radiation[2]. Among these changes is a marked increase in bile secretion. This suggested the use of such bile: (a) in filtration experiments, as an addition to the material to be filtered, and (b) as a preliminary injection in order to damage the tissues at the site of a subsequent inoculation of filtrate.

The methods (see the accompanying table) have yielded a number of tumours of which two are known to have been produced by cell-free materials. Filtration was carried out on lines previously described[3] and it was found that the addition of bile to a concentrated extract of tumour produces quick and easy filtration.

		Group	Method of removal of bile from excised gall bladder	Number of mice	Tumours
1	One injection of bile only	*A*1	By puncture, syringe or capillary after scalding gall bladder 3 times	16	1
		*B*1	By puncture. Bile then filtered	23	0
	One injection of filtrate of tumour extract with bile	*C*		21	0
			Total, *A*1, *B*1 and *C*	60	1
2	Bile injected 1–4 days before filtrate of tumour extract with bile	*A*2	Same as *A*1	31	14
		*B*2	Same as *B*1	39	2
			Total, *A*2 and *B*2	70	16

It will be seen that the experiments in the two classes are arranged in pairs: *A*1 and *A*2, *B*1 and *B*2, in which the technique is similar. The *A*2 group show by far the highest proportion of positive results (14 in 31); this can scarcely be due to the inclusion of tumour cells with the bile, for the injection of bile alone obtained in exactly the same way (*A*1) gave only one positive in 16. In the $B2$ group the presence of cells was excluded by filtration of all materials injected, and the number of positive results (2 in 39) which occurred, although low, was higher than that (2·5 per cent) found in earlier experiments with tumour filtrate alone[3]. The much smaller number of tumours in $B2$ than $A2$ may be due, if contamination with cells in $A2$ can be excluded, to a considerable reduction in the amount of some tumour-producing agent caused by: (*a*) loss of the agent on the membrane and filter apparatus; (*b*) oxidation taking place during prolonged collection of the bile and filtration.

Autocatalysis and Blood Coagulation

THE autocatalytic behaviour of blood coagulation is thought, by several authors, to be due to the autocatalytic formation of thrombin from its precursor prothrombin[1]. So far, thrombin seems similar to the enzymes studied by Northrop and co-workers[2].

Experiments have now shown the reaction to be a more complicated one. In a neutralized solution containing purified fibrinogen and prothrombin, together with calcium chloride, it was not found possible to obtain a formation of new thrombin upon inoculation with preformed thrombin. By inoculation from such a mixture to a new solution, and so on, the clotting power was exhausted in the course of a few passages, which is in contrast to the results obtained with fresh plasma as a clotting medium[3]. The clotting power of the mixture was in accordance with the amount of thrombin added, and only the further addition of thrombokinase yielded new amounts of thrombin. In fresh plasma it was possible, by the addition of small amounts of acetic acid, to inhibit the autocatalytic properties.

Thrombin thus does not seem to be formed by an autocatalytic reaction in the common sense, and the autocatalysis takes place only in native plasma.

Isolation of Oestrone from the Adrenal Gland

IN a former communication to Nature[1] reporting the isolation of progesterone and allopregnanolone from the adrenal gland, reference was made to the work of Engelhart[2]. He obtained lipoid extracts of this gland which produced oestrous and progestational effects in the uterus of the immature rabbit. Later, Callow and Parkes[3], who confirmed these findings, fractionated the active materials by the method of Allen and Meyer[4].

Now a further investigation of the oestrogenic principle of the adrenal has been made, using a concentrate kindly supplied by N. V. Organon Oss to Dr. A. S. Parkes, who placed it at my disposal.

The concentrate, from which the adrenalin and the greater part of the cortical hormone group of steroids had been removed, was saponified, practically all the oestrogenic activity being found in the saponifiable material. This was separated into non-ketonic and ketonic fractions, both of which were oestrogenic. Oestrone has been isolated from the latter as the benzoate, melting at 215–217° alone or at 215–216° when mixed with authentic oestrone benzoate (melting point 215–217°).

A bioassay on the isolated benzoate, carried out by Mr. Emmens of the National Institute for Medical Research, gave an 80 per cent response in a group of ten mice, each receiving a single dose of 0·5 γ in nut oil. Authentic oestrone benzoate under similar conditions gave a 90 per cent response.

Full experimental details of the isolation of the oestrone will be published in full elsewhere. The oestrogenic material in the non-ketonic fraction is still under investigation.

Precipitation of Protein Fractions in Solutions Particularly Poor in Proteins

THERE are some technical difficulties in the handling of small amounts of protein fractions precipitated with neutral salts, such as sodium sulphate, in the usual way, because of the comparatively large quantities of liquid to be employed. We have therefore made attempts to find a method permitting the precipitation of the different proteins by direct addition of the salt to the protein solutions in the desired proportion.

Experiments have been made with human blood serum as well as with virus solutions of Shope rabbit papilloma. As a control, we employed the usual method of precipitation: addition of 30 parts of the salt solution in the desired concentration to 1 part of protein solution. After allowing to stand for about three hours, filtration was performed through Schleicher-Schüll No. 602 filters; the total and residual nitrogen content in the filtrates was controlled by micro-Kjeldahl estimations.

For the new method we added a weighed amount of the dry, well-powdered salt (sodium or ammonium sulphate) extremely slowly to the protein solution with continuous shaking, avoiding in this way an abrupt increase of concentration; if necessary the manipulation was carried out in a water-bath. Thus we needed about 30 minutes for dissolving 1·5 gm. in 5 c.c. of protein solution. Three hours afterwards, filtration and estimation were done as usual.

By this method a quantitative yield of the precipitated protein can easily be obtained, and sedimentation of large amounts of liquid in big centrifuges can often be avoided.

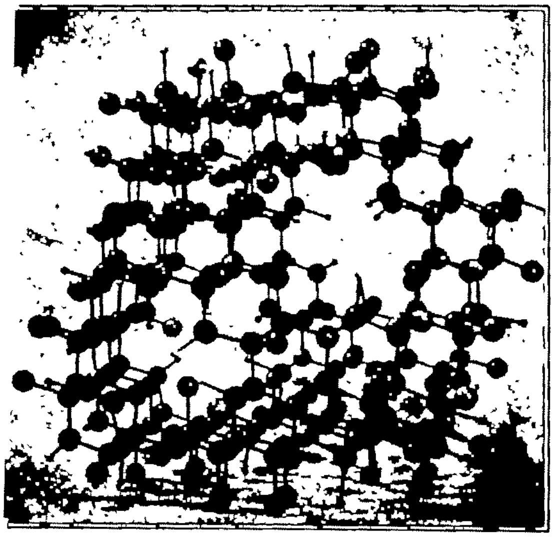
The Tuberculin Protein TBU-Bovine (523)[1]

As has been increasingly emphasized lately, the idamental problem of protein structure is to explain existence of very large but chemically and ysically well-defined molecules. It is evident that y two-dimensional pattern of amino-acid residues l either be incapable of folding to form a closed ge-like structure, or will form such a structure only certain ways which correspond to definite numbers residues. Irrespective of the particular nature of e characteristic protein fabric, the idea of closed uctures (such as a cage[2] or torus or surfaces of gher connectivity) has therefore been offered as an planation of the existence of these protein megaolecules.



The particular fabric known as the cyclol fabric as been shown to yield cage structures C_1, C_2, . . . he skeletons of which are built on a ground plan f 72, 288, . . . residues, and it has already been hown that the actual numbers given by Svedberg or his molecular weight classes correspond to simple r compound C_1, C_2, . . . units or to colonies of C_1 units alone[3]. As was pointed out, the smallest f these classes corresponds to a dimeric structure nade up of two C_1 cages. It is therefore of interest to find that, in studies of the tuberculin protein moleules, a protein, TBU-Bovine (523), with molecular weight about 10,000, has been isolated, which is homogeneous in sedimentation, diffusion and electrophoresis. Such a molecular weight is of the right order of magnitude to correspond to a single C_1 structure.

Structure of Aromatic Polynitro Compound-Hydrocarbon Complexes

THE most obvious evidence of interaction of some kind between aromatic polynitro compounds and other aromatic substances is the isolation of many crystalline compounds containing the two components in simple molecular proportions. The evidence, particularly of colour and heat of interaction, points to something stronger than mere van der Waals' binding between the molecules, but it is not certain that they are linked by ordinary valency bonds. Existing X-ray work[1] and the theoretical work of Briegleb[2] are against this type of bonding.

We have examined the crystal structures of a large number of these compounds and find that, although the molecules are arranged in parallel planes, there are usually at least two sets of planes inclined to each other, and owing to overlapping of many atoms in projections of the structures, a clear decision as to the exact position is difficult. We have now, however, found a structure in which this difficulty is removed and a convincing proof provided that there are no bonds between the molecules.

The 1 : 1 molecular compound of picryl chloride and hexamethylbenzene is orthorhombic: $a = 14 \cdot 0$, $b = 9 \cdot 0$, $c = 15 \cdot 4$, and the space group *Amam* or *Ama*. There is no pyro-electric effect detectable by the liquid air method; the crystals therefore probably have a symmetry centre (space group *Amam*), but the conclusions we draw are valid for both space groups. Patterson analyses and general space group considerations show that all picryl chloride molecules lie in two sets of planes parallel to (100) separated by a distance of 7 A. All hexamethylbenzene molecules lie in two sets of planes parallel to and halfway between these, that is, separated from them by 3·5 A. This is supported by optical properties and by quantitative agreement of calculated and observed relative intensities of reflections *h*00. In this special case there cannot be any valency bonds between the nitro compound and the hydrocarbon whatever the arrangement of the molecules in their own planes. Anomalous X-ray diffraction effects suggest the possibility of a cell of three times the *b* dimension and show that there is some degree of disorder in the structure. Comparison with the corresponding bromide and iodide shows that it is the nitro molecules that are disordered. Of particular significance is the fact that the structure of the hexamethylbenzene layers is identical to within fractions of an angstrom unit with that of a single layer in the crystal of hexamethylbenzene itself.

A more detailed account of this work will be published elsewhere.

Classical Dynamics of the Meson

THE interaction energy between two nuclear particles in the case of interaction transfer by single Bose particles, that is, $g^2 e^{-K_0 r}/r$, can be obtained either by identifying it classically with the Green's function of, for example, $\Delta\varphi - K_0{}^2\varphi = 0$ $(K_0 = mc/h)$ for the field of mesons transferring the interaction, or by a computation on the lines of quantum electrodynamics. The latter method leads to the same result, because the quantum-mechanical expression for interaction,

$$g^2 \frac{\varphi(\vec{r_1})\ \varphi(\vec{r_2})}{S},$$

where $\varphi(\vec{r_1})$ is potential acting on the first particle, and S is the operator of the Schrödinger equation describing the interacting particles, reproduces the bilinear Fourier expansion of Green's function (Mercer's expansion), just as in the electrostatic case[1].

There is another classical way of arriving at the Coulomb formula, when one starts, namely, not from the Laplace equation, but from $\Delta\varphi - \ddot{\varphi}/c^2 = 0$. The solution of the wave equation in functions of the four-dimensional distance $R = \sqrt{r^2 + x_4^2}$ is $\varphi = 1/R^2$, which not only leads to the r^{-1} law, upon integration over x_4, but also yields in the known manner retarded potentials, etc.

It may be of interest to get the similar fundamental invariant solution for the case of Proca equations. The solution of the equation $\Delta\varphi - \ddot{\varphi}/c^2 - K_0^2\varphi = 0$ is found to be

$$\varphi = \frac{K_0}{2} \frac{H_1^1(iK_0R)}{R},$$

where H_1^1 denotes Hankel's function of the first kind and of the first order; this special solution has the right limit at $K_0 = 0$. Upon integrating this solution over the time (x_4) in the static case where r is a constant, for the point heavy 'charge' g, we obtain the required expression, e^{-K_0r}/r.

This method of reasoning not only gives a new deduction of the Proca-Yukawa potential but can be used also for investigation of other special cases of classical 'mesodynamics', such as the analogue of retarded potentials, rate of emission of mesons by heavy particles, etc.

The most important problem is the construction of a classical model of the heavy mass by means of a mesonic field in the same manner as the electronic mass is built up from an electromagnetic field. We may mention here only three possible lines of attack on this problem: (1) the rough method of introduction of a radius d of the heavy particle. We get easily the following expressions for the self-energy of a heavy particle in the cases of a surface and a volume[2] 'charged' heavy mass respectively:

$$E_s = \frac{1}{2} g^2 \left(\frac{1}{d} + K_0\right) e^{-2K_0d};$$

$$E_v = \frac{9}{4} \frac{g^2}{d^6K_0^2} \left\{\frac{2}{3}d^3 - \frac{1}{K_0}\left(d^2 - \frac{1}{K_0^2}\right) - \frac{1}{K_0}\left(d + \frac{1}{K_0}\right)^2 e^{-2K_0d}\right\}.$$

The empirical value $d \sim 10^{-13}$ cm. gives too small an energy or heavy b mass. (2) Dirac's method of direct omission of infinite terms in the expression for the electronic mass can be applied also in our case of heavy mass and mesonic field. Clearly, the non-electromagnetic and non-mesonic fields respectively must be introduced here in some manner, as it is impossible to obtain the equations of motion from linear Maxwell and Proca equations. (3) The last mentioned extra-field playing the part of Poincaré's pressure can be associated with the non-linearities of the field. Following the Born-Infeld theory, say, as the most elaborated non-linear scheme, we can construct non-linear generalizations of Proca equations, which seem to be particularly appropriate in the case of neutral mesons.

We shall discuss in *Journal of Physics*[3] the bear of this non-linear limitation of quantum mecha on cosmic ray phenomena, as well as other det of the above considerations.

A Pure Strain of *Trichomonas eberthi* in Tissue Cult

IN May 1937 we found in an explantate fron spontaneous leukæmia tumour in a fowl numer specimens of *Trichomonas eberthi*. Since then have maintained the strain continuously on colon of chicken fibroblasts. About 180 passages he been made up to the present time.

The flagellates are being cultured together wi chicken fibroblast in hanging drop cultures accordi to the standard tissue culture technique of Carr For the culture medium, we used chicken plas and chicken embryonic extract in 10 per cent dilutio As a rule the passages are made every third da To every passage a piece of an embryo chick's hea or a piece of a pure fibroblast culture is added as substitute for the cells which are gradually destroye

T. eberthi multiplies intensively among the fibr blasts and in the immediate neighbourhood of t tissue. They slowly liquefy the plasma coagulu while spreading towards the periphery. After period of forty-eight hours, the culture is pervad and surrounded by a dense mass of active flagellat

The presence of living cells is essential for t permanent culture of this species in the plasm embryonal coagulum. Several attempts were ma to culture *T. eberthi* in the same medium in t presence of cells which had been previously kill by X-rays or heat, but all of them failed and t flagellates died out in the second passage. On t other hand, when *T. eberthi* was cultivated in dilut embryonic extract alone, rich cultures were obtaine up to the twelfth passage during forty-five days.

"Introduction to Modern Genetics"

WE are surprised at the review of Waddington' "Introduction to Modern Genetics" by Dr. F. W Sansome in NATURE of June 17, p. 1002. We a at a loss to know what the reviewer means when h says that Waddington's book does not "contain balanced statement of modern genetics". It appea to us to be much the most satisfactory book on th subject written in recent years. Doubtless the scop could have been enlarged (for example, the treatment of adaptation and the mechanisms of speciatio seems in places inadequate), and equally doubtless book written ten years hence would adopt a differen balance of subjects. Meanwhile, however, the mos conspicuous feature of recent advance in genetics ha the laying of a firm cytological foundation, and ur opinion it is important that this should be y presented at the outset in any text-book. iological genetics has not yet reached the point which simple general principles have emerged; even so, Waddington's treatment of it appears e the best available in any general text-book.

n the interests of genetics and of biology as a le, we hope that Waddington's book will be ely used both as a general account for teachers research workers and as a text-book for advanced dents.

J. B. S. Haldane.
J. S. Huxley.
H. J. Muller.

---

r. Waddington's book was reviewed as an troduction to Modern Genetics". The writers of above letter would seem to agree with me in not ommending it as an introductory book, but her as a book for teachers, research workers and vanced students.

If we consider the book not as an introduction but as a presentation of modern genetics, I still consider that the book stresses the cytological approach to the problem at the expense of formal genetics. While fully aware of the importance of establishing the relationship between chromosomes and genes, I think this might have been made clear in less space than that allotted (one half to one third of the book). The space so saved could have been used with advantage in providing more experimental and biological data (little of which are given) and some idea of the methods used and difficulties encountered in obtaining them. If phenomena such as gametic and zygotic viability and genetical and biological evidence had been more fully referred to, I feel sure that the book would be more sympathetically received by the general biologist.

The cytological approach is, as stated in my review, well presented and probably the book will be most used by advanced geneticists who require information on modern cytological theories.

F. W. Sansome.

June 28.

Points from Foregoing Letters

A. C. Chibnall, M. W. Rees, G. R. Tristram, E. F. illiams and E. Boyland are unable to substantiate e recent claim of Kogl and Erxleben that the tamic acid given on acid hydrolysis by the protein malignant tissues is partially racemized. The oducts isolated by the former workers from Crocker rcoma and from two human carcinomas had the rmal specific rotation of + 31·6° in 9 per cent drochloric acid.

L. Hahn and G. Hevesy state that a minor part of e phosphatide molecules present in the corpuscles changes readily with those present in the plasma; large part of the phosphatide molecules present in e corpuscles is not replaced during the lifetime of e corpuscles.

According to experiments by M. Hoffer and T. eichstein, a purified ether extract from liver, the only tive constituent of which was probably pantothenic id, produced a small increase of growth in rats fed a diet free from filtrate factor. Nearly the same ffect could be produced by β-alanine.

Experiments with rats carried out by a group of vestigators from the Lister Institute and from the niversity of Manchester indicate that the rat requires t least six different factors contained in the vitamin B omplex: aneurin, riboflavin, vitamin B_6 and three rther substances at present unidentified.

I. Banga, S. Ochoa and R. A. Peters report on rther results of their analysis of the pyruvate oxidaion system in brain. Cocarboxylase, fumarate, organic phosphate, adenylic acid and cozymase are omponents of the system. A cycle of phosphorylation ppears to be involved in the oxidation of pyruvate eyond the stage of oxidative decarboxylation.

Excessive bile production occurs in mice grafted ntraperitoneally with a sarcoma, which bile, hen utilized in filtration experiments, has been ound by Mrs. L. Dorothy Parsons to promote tumour production. Of the sarcomas obtained, two were produced by cell-free materials.

T. Astrup finds that the blood-clotting enzyme thrombin is not formed by an autocatalytic reaction in the usual sense, since thrombokinase has to be added in order to form new amounts of thrombin.

The isolation of oestrone from the adrenal gland by D. Beall adds another compound to the long list of steroids isolated from this organ. This is the third tissue from which oestrone has been obtained, it having been isolated previously from sow ovaries and human placenta by Doisy and his co-workers in the United States.

Peter Ladewig describes how small amounts of protein fractions can be precipitated directly by dry powdered neutral salts.

Dorothy Wrinch points out that the molecule of the tuberculin protein TBU-bovine, which is homogeneous in sedimentation, diffusion and electrophoresis, has a molecular weight of 10,000, of the right magnitude to correspond to a single C_1 cage structure.

H. M. Powell and G. Huse state that in the molecular compound of picryl chloride and hexamethylbenzene the component molecules are arranged in parallel layers. The hexamethylbenzene layer is almost identical with a single layer in the structure of the hydrocarbon itself, but there is partial disorder in the picryl chloride layer.

It is suggested by D. Iwanenko that a classical theory of the mesonic field may be useful for purposes such as the construction of various potentials or the discussion of the nature of heavy mass.

E. Tenenbaum states that he has been able to grow the flagellate *Trichomonas eberthi* in hanging-drop cultures of chicken fibroblasts, using chicken plasma and chicken embryonic extract in 10 per cent dilution as culture medium.

RESEARCH ITEMS

Family Life of Rajputs

IN the foot-hills of the Himalayas north-east of Dehra Dun is the Doon district occupied by Rajputs who came from farther south in comparatively recent times. Dr. D. N. Majumdar (*Calcutta Review*, March 1939) has given an account of the family life of these people, who are tall and fair with long heads, leptorrhine noses, hazel or blue eyes, curly hair and jovial disposition. They have maintained the purity of their Indo-Aryan descent although surrounded by the Mongoloid Gharwalis and other hill tribes. They build substantial timber houses of three or four stories against the severe winters and have small terraced farms with cattle and sheep. Like the Todas and Kotas and the Tibetans, they are polyandrous, several brothers having one or more wives in common under the same roof. The eldest born child is conventionally fathered upon the eldest brother, the next child on the second, and so on. In case of partition the eldest brother receives the largest share of the property. In a village investigated, the number of married males was four times that of the married females. The number of children is low, four or five brothers between them having only three or four children, and there is a preponderance of male children. The number of barren women is high, divorce of the wife is frequent and is followed by remarriage. A woman who has produced children fetches a much higher bride-price than one who has not. This fraternal polyandry they believe is derived from their Aryan ancestors, the Pandaras, but Dr. Majumdar gives reasons for thinking that it has been borrowed from other sources more recently. He also agrees with Westermarck that there are other causes of polyandry besides a paucity of women.

Morphological Characters of Bacteria and Viruses

IN his presidential address delivered to the Royal Microscopical Society last January, entitled "Towards the Smallest Living Things", J. E. Barnard contrasts the morphological similarities and differences that occur in micro-organisms of regularly decreasing size (*J. Roy. Micro. Soc.*, 59, 1; 1939). As the smaller objects are beyond the limit of visual microscopic resolution, the contrasts have been made by means of ultra-violet photomicrographs taken with a wave-length of 2750 A., some by transmitted light, others by dark-ground illumination. From a study of these microscopical images, Mr. Barnard concludes that some at least of the filterable viruses are similar to some of the recognized bacteria. No viruses appear to be exactly similar to ordinary bacilli, but the resemblance of some viruses to cocci is much closer. Thus, ectromelia and vaccinia viruses are essentially coccoid in form. There is, however, a change with influenza and herpes viruses, which are types of virus growing in dense opaque masses, and the individual particles or units of which these are made up are very difficult to identify, as their size is very small, being less than 50 μμ. It is therefore suggested that below some size, to which a precise value cannot yet be assigned, there is a change in constitution—not so much an alteration in form as a change in behaviour. These animal viruses may at th stage bear a closer resemblance to the plant virus which recent work suggests are chemical in natu

Mutant Body Colours in a Parasitic Wasp

ANNA R. WHITING has recently described h investigations into this subject and with reference the species *Habrobracon juglandis* (*Proc. Amer. Ph Soc.*, 80, No. 1; January 1939). It appears that wil type individuals vary in colour from honey-yell to almost black. This wide range of colour variati is confusing to the taxonomist, who is prone to l much stress upon colour in diagnosing species. Ter perature is of prime influence in connexion wi coloration, the higher temperatures producing mo yellow and the lower temperatures more blac Heredity also plays some part in the process, for t reason that some races may differ consistently their coloration when subjected only to a consta temperature. In the type known as honey-yellow exception is found to the rule that more black deposited under low temperatures. The various fac are discussed in the light of Wright's theory of pi ment formation in mammalian hair. It was four that this theory fits the facts observed in *Habrobrac* so well that, using it as a basis, the appearance double and triple recessives was predicted with con siderable accuracy before they were actually obtaine The various types referred to are well figured in th accompanying nine coloured plates.

Tobacco Necrosis Virus

N. W. Pirie, K. M. Smith, E. T. C. Spooner an W. D. McClement (*Parasitology*, 30, 543; 193 isolated two nucleo-proteins with similar chemic composition from the leaves of tobacco plants ir fected with tobacco necrosis virus (*Nicotiana* virus II One of them was crystalline and had a sedimentatio constant of 130×10^{-13}, the other was amorphou and its principal component had a sedimentatio constant of 58×10^{-13}. Each preparation infecte plants at a dilution of 1 in 10^{6} and precipitate specifically with serum at a dilution of 1 in $3 \cdot 2 \times 10$ The nature of the difference between preparation in the two states is obscure, and it has not bee possible to convert one into the other.

Vacuolar Stain in Fungal Hyphæ

S. R. BOSE, of the Carmichael Medical College 1 Belgachia Road, Calcutta, has found a very fain pinkish stain in the vacuoles of very young hyphe not only of *Polypores* but also of diverse groups o fungi like *Mucor*, *Rhizopus*, yeast, *Penicillium Ascoidea*, *Aspergillus*, *Fusarium*, *Cladosporium*, *Beau veria*, etc. (*Curr. Sci.*, 8, No. 4, April 1939). It doe not agree with the tests of anthocyanin as found i higher plants. The nature of the pigment remain unknown. Evidently the stain has some connexio with the metabolic stage of the fungus, for it has bee found only in actively growing hyphæ and becomin scarce in very old hyphæ and older cultures. Prof Bose will be glad to have the experience of othe workers on the point.

Chromosome Structure

R. RUGGLES GATES has published a valuable review of chromosome structure accompanied by a bibliography to recent work (*J. Roy. Micro. Soc.*, 58; 1938). There is considerable evidence that appearances which have previously been described as chromomeres may in many cases be an optical effect due to spiral coiling of chromonemata. Whether all cases of chromomeres will finally be interpreted in this way is doubtful. Direct observation also seems to show that the chromonemata are at least double in anaphase and telophase, quadruple in metaphase. The light thrown upon such problems by X-ray treatments are at variance and of doubtful reliability until more is known of the exact effects produced in this way. A relatively new line, possibly of considerable value in genetics and analysis of species, is the recognition of the universality of satellited chromosomes and their relation to nucleoli. The probable fact that a primary diploid usually has two *SAT*-chromosomes, opens possibilities of recognizing the presence of polyploidy by more than two nucleoli at telophase, the number of bivalents attached to the nucleolus at zygotene to diakinesis and the presence of secondary pairing.

Attachment for a Milne-Shaw Seismograph

AN ingenious and interesting addition to a Milne-Shaw seismograph has been fitted by J. H. Peters at the Observatory of the University of Hawaii in Honolulu (*Bull. Seis. Soc. Amer.*, 29, No. 2, 341–343; April 1939). The need for a strong motion instrument was particularly felt on the occasion of the Hawaiian earthquake of January 22, 1938, which disconnected the recording mirror, but as such instruments were not immediately available, additions to the existing equipment were made on the spot at very little cost. The instruments originally had $T = 12$ sec., $V = 150$ sec. and $\varepsilon = 20:1$, recording photographic, and paper speed 15 mm./min. This was constituted for teleseismic work, which is the main need as strong local shocks are rare, but should local shocks occur the magnification was too great for photographic recording of high accelerations, and the paper speed too slow for recording the short periods. Recording mirrors have now been fixed to the top of a 2-inch long aluminium stem secured to the boom less than one half inch from the point of rotation and practically at the centre of the column. Lamps and auxiliary recorders have been placed at right angles to the boom line at a distance of about 23 inches from the mirrors to give a satisfactory magnification. The new recording works independently and in addition to the old recording which has been maintained, and the new would continue to function should the original be disconnected by a strong local shock. The new attachment is not constantly recording but is switched automatically into operation as soon as a local shock occurs which is strong enough to actuate the control. The new device should form a very valuable addition to the observatory's equipment.

Earthquakes registered during February 1939

ACCORDING to E. Peterschmitt (*Bull. Bur. central séismol. Strasbourg*) there were 174 earthquakes registered by seismographs throughout the world during February. The largest number in one day was fourteen on February 2, and there was only one day on which none was registered, namely, February 22. Some of these were recorded by only one station, several were registered by about six stations and nine were of such magnitude that it was possible to determine the epicentre, depth of focus and initial time accurately. These were: February 2, epicentre south-east of Tripoli, February 3, epicentre near Solomon Islands, February 5, Venezia Giulia and Dalmatia (Italy), February 6, a repetition of February 5. February 9, near Central America, February 11 near Mugello (Italy), February 16, north Japan, February 17, Struma Valley, south Bulgaria, and February 24, south Alaska.

Double Oxy-chlorides of Rhenium

WHEREAS very little is yet known concerning the chemistry of masurium (element 43 and Mendeléeff's eka-manganese) many compounds of rhenium (element 75, dwi-manganese) have been described. The latest are some oxy- and hydroxy-chlorides obtained by Jezowska and Iodko (*Roczniki Chemji*, 19, 187; 1939) by reduction of per-rhenic acid with hydrogen iodide. These investigators state that reduction proceeds to quadrivalent rhenium at room temperature without the presence of excess of hydrochloric acid. Among the compounds isolated are ammonium, potassium and rubidium salts having the general formula $X_2[Re(OH)Cl_5]$. These hydroxy-chlorides are easily converted into oxy-chlorides of composition corresponding with the formula $X_4[Re_2OCl_{10}]$, whilst with excess of concentrated hydrochloric acid and at elevated temperatures the normal rhenichlorides, X_2ReCl_6, are formed. A quinoline oxy-chloride was prepared in addition to the alkali salts mentioned above. Since the same reactants can give rise to several different products, some difficulty was experienced in isolating these oxy- and hydroxy-salts in a pure state, a careful control of conditions being essential.

Fission of Rotating Bodies

LIEUT.-COL. K. E. EDGEWORTH has criticized (*Mon. Not. Roy. Astro. Soc.*, 99, 3; January 1939) some of Dr. R. A. Lyttleton's views (in particular those which appeared in *Mon. Not. Roy. Astro. Soc.*, 98, 8; 1938) regarding the fission of rotating bodies. Lyttleton believes that binaries did not originate by fission, as it seems probable that the smaller body would escape altogether from the larger, rotational energy being sufficient in certain conditions to drive the bodies apart from each other's influence. Edgeworth points out that such a process would involve repulsive forces for a time, such forces exceeding the force of gravity, but there is no known mechanism by which such forces could be produced. He discusses the theory that fission might lead to the production of a satellite and admits the possibility of a small portion of the detached material escaping the disintegrating effects of the Roche limit and so forming the nucleus of a satellite. The disintegrated material inside the Roche limit would gain angular momentum owing to the ellipsoidal shape of the larger mass, and for this reason would be driven outward and probably absorbed by the nucleus of the satellite, assuming that such a nucleus existed. Contrary to Lyttleton's view, Edgeworth thinks that the final stage to which a rotating body would attain would be two separate bodies revolving about each other in nearly circular orbits, but still subject to mutual interference in the form of tidal friction.

ROTHAMSTED EXPERIMENTAL STATION

ANNUAL FIELD DAY

ON June 28, the annual field day and inspection of the laboratories was held at Rothamsted, Lord Radnor, chairman of the Lawes Agricultural Trust Committee, presiding. There was a large attendance representing agriculture and the allied industries. Sir E. Kaye le Fleming, chairman of the Council of the British Medical Association, was the chief guest. His presence was a welcome sign that medical men are deeply concerned with matters of human nutrition, and recognize that a prosperous agriculture based on a fertile soil is essential for the supply of home-grown 'protective foods' on which the well-being of our town population depends. This common ground between medicine and agriculture had been thoroughly explored two months previously in a national conference organized by the British Medical Association in which nutritional experts and agricultural scientists took part (see NATURE, of May 6, p. 745); the proceedings at Rothamsted showed that both sides desire this co-operation to continue and develop. The main position, as Sir Kaye pointed out, is clear; doctors are agreed that a high proportion of the population do not enjoy a diet sufficient for the highest physical well-being, and nothing but good could come from a determined attack on this problem. From the medical side, the framer of agricultural policy needs definite information as to the kinds and qualities of food stuffs required to build up an adequate diet, and this information is apparently now available. It is for the agriculturist to show how commodities of he necessary standard may be produced with conomy of effort and the maintenance of the land.

In his survey of the activities of the Station, Sir ohn Russell mentioned that some work had already een carried out in the Dunn Nutritional Laboratories t Cambridge on certain aspects of the vitamin ontent of the produce of the Rothamsted plots. ut so far there has been no confirmation of the ew frequently expressed that the nutritive value produce grown with organic manure is superior to at grown with artificial fertilizers. The produce of e classical fields should provide excellent material settling points such as these.

An increasing amount of experimental work at thamsted is concerned with the action and value rganic manures. Studies are in progress with straw ts many forms, with turf obtained by the ploughing of grassland, with green manures, and with town se. An extensive investigation of poultry manure been completed, and work on wastes and sewage dge is in prospect. So far, yield determinations e been the chief measurements; but the much e difficult questions of quality and nutritional e can scarcely be ignored.

he tour of the farm, always an important part e proceedings, affords an unrivalled combination e oldest and the newest in field experimentation. dbalk, carrying an excellent crop of wheat this showed the striking effects of the manurial ments begun by Lawes and Gilbert ninety-six ago and continued ever since, the plots gaining rather than losing interest from the periodical bare fallows recently superimposed upon them. The field is much studied now, not simply as a demonstration of manurial principles, but as a guide to the practical problems of corn growing under semi-continuous conditions. Many wheat growers would be quite satisfied with crops as thick and healthy as Broadbalk has recently carried, for the foot-rot diseases, so troublesome when wheat is grown too frequently on the lighter soils, are seldom serious on the clay loam of the classical field. The continuous barley on the adjoining Hoosfield tells the same general story as Broadbalk, with important differences that are readily visible; the barley, for example, is more sensitive to phosphate deficiency than the wheat but less affected by potash starvation.

Passing on to the modern experiments, the visitors inspected several of the new designs set out to measure fertilizer effects on a sequence of crops. These are necessarily more complex than experiments lasting for a single year only, since special provision must be made to take account of the seasonal factor. One of the modern experiments dealing with alternative systems of cropping newly ploughed up grassland, aroused much interest. A series of excellent crops were on view on land that was in good turf so late as February of this year. Fertilizer effects were also on test, as well as several soil insecticide treatments against wireworm. In view of the official encouragement now being given to the breaking up of grassland, this type of experiment is of the greatest importance.

An indoor programme followed. Investigations in the laboratories link up with the farm work in many directions. Thus 'take-all', one of the foot-rot diseases of cereals, is intensively studied in the Plant Pathology Department, where many of the conditions of the survival of the fungus in the soil have been worked out, and control methods are being developed. In the Entomological Department a technique for measuring the wireworm population of the soil has been perfected and used to assess the value of the various soil insecticides tested in the plots. Various methods put forward for predicting the manurial requirements of soils on the basis of their chemical analyses are being examined in the Chemical Department. A wider range of soils than the Rothamsted Farm can provide is necessary for this work, and in recent years an increasing number of outside centres have been established, each providing the results of a precise and comprehensive fertilizer test and the corresponding sample of soil for laboratory examination.

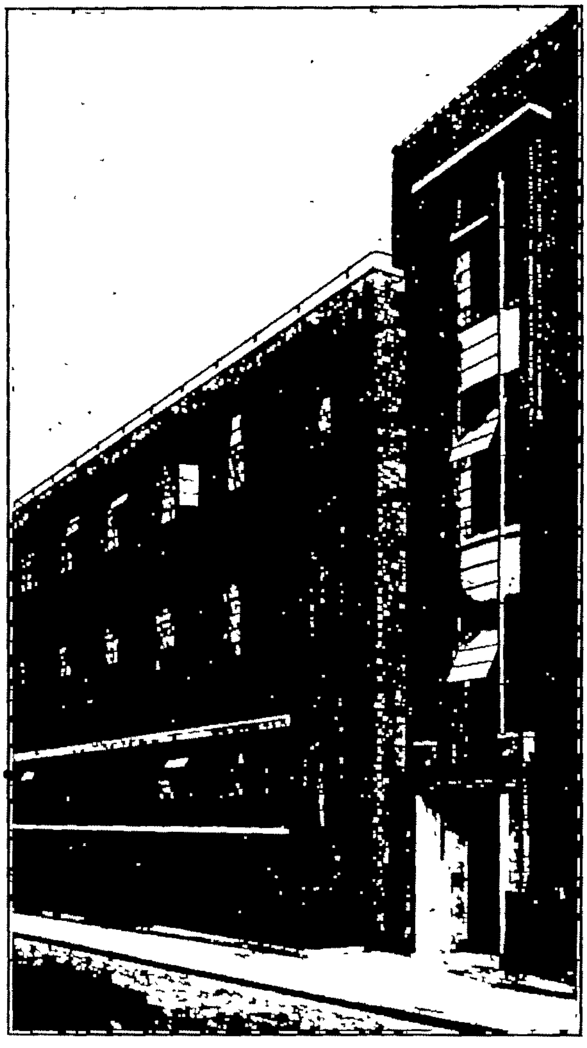
The Rothamsted Centenary is due in 1943 and the Committee proposes to celebrate it by putting the laboratories, farm buildings and other equipment into complete order for the work that awaits them. The Director announced the present position of the Appeal Fund, and said that although good progress has been made in very difficult times, £7,000 is required to complete the first part of the scheme costing £60,000.

BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION

By Dr. H. Moore, C.B.E.

SOME idea of the importance of the non-ferrous metals may be gained from the value of the world's annual production which, if gold is excluded, is not less than £250,000,000. Another illustration is provided by the dependence of the electrical industry on copper and of aircraft production on aluminium and magnesium. The many uses of lead, nickel, tin and zinc are familiar, and the application of three of these four metals as protective coatings for steel illustrates the resistance to corrosion of non-ferrous metals. The British Non-Ferrous Metals Research Association thus has a wide field for its work. It is among the larger of the research associations formed soon after the Great War as part of the Government's policy of stimulating scientific research applied to industrial progress, and about one third of the Association's annual expenditure of more than £30,000 on research and related activities is still provided by Government grant.

The Association's investigations were at first carried out at the National Physical Laboratory and at metallurgical research laboratories elsewhere, but the proportion of extra-mural work has diminished with the growth of the Association's own scientific staff, and two years ago a scheme for the erection of a modern building, near Euston Station, was adopted. The Association owns a freehold site of 13,000 square feet, of which one third is held for future extension. In the choice of location, accessibility was held to outweigh the advantage of the lower cost of suburban land, and the situation is convenient for the many members in the Midlands who use the northern London terminal railway stations. The number of member companies is not far short of three hundred and includes most of the producers and manufacturers of non-ferrous metals and their products in Great Britain, and also many large users.



New Laboratories of the British Non-Ferrous Metals Research Association

The laboratories, which accommodate a total staff of about seventy, comprise the older four-story building, formerly rented, the adjacent new block of about the same shape and size, and, in the space between, a glass-roofed melting shop. The total working floor space is about 20,000 sq. ft.

The new building, designed by Mr. J. R. Smith of Messrs. Munby and Smith, is a four-story steel-framed structure with brick panel walls. It has a 90 ft. frontage in Euston Street and is 32 ft. in width.

The extensive use of non-ferrous metals exemplifies their advantages in modern building. The heating installation, electrical conduits, hot- and cold-water supplies to laboratories, soil and waste plumbing and principal rain pipes and hoppers are all in copper; the water supplies to laboratories in *BNF* ternary lead alloy No. 2; while nickel silver, bronze and anodized aluminium are used for door furniture, water-fittings, etc.

The arrangement of service pipes and conduits has been designed with particular regard for economy in space, clean unencumbered ceiling, wall, and floor surfaces and accessibility. Each laboratory is fed from ducts running vertically, in the window piers, the full height of the building. Ample provision has been made for A.C. and D.C. electricity supply for power, furnaces and light. Heating is by low-pressure hot water on the 'invisible panel' system and is thermostatically controlled.

One main section of work deals with the influence of melting and casting conditions on the freedom of castings and ingots from cavities, caused by gas evolution or by shrinkage, and from segregation and other troubles. The Association's de-gassing process for aluminium alloys is widely used in manufacture, and the problem of soundness in castings is now being tackled for the tin bronzes and the nickel silvers. Segregation and shrinkage are being investigated in aluminium alloys in the first instance. The facilities of the melting shop providing for work on these subjects include coke fired, gas fired and electric resistance (silit rods) crucible furnaces melting 100–120 lb. copper and a high-frequency furnace. There is also a large electric resistance annealing furnace.

The mechanical testing laboratory occupies the lowest floor of the new building. The constant-temperature room (480 sq. ft.) at one end is thermostatically maintained at 20° C. ± 0·3° C. by circulation of air, heated or cooled according to the outside temperature, and is equipped for creep tests. The very complete spectrographic equipment employed in the Association's work on quantitative spectographic analysis of metals and alloys is housed in the large physics laboratory, the other equipment of which includes that designed by the Association's staff for the determination of thermal conductivity and of optical reflectivity. Good provision is made, in other rooms, for the preparation, examination and photography of metallographic specimens, for pyrometry and heat treatment, and for chemical analytical work.

The top floor of the older building is devoted to corrosion research, a subject in which the Association's work tends always to increase. Condenser tubes, on which work has proceeded for so many years, have ceased to be a corrosion problem fo ordinary conditions of service because of the genera use of tubes made of the Association's aluminium bras or other highly resistant alloys developed by maker but the more severe corrosive conditions sometime encountered—bacterial action playing a part no infrequently—are the reason for work designed t produce tubes still more resistant. Other corrosio investigations are concerned with lead, copper, zin and galvanized material, and at least five hundre corrosion tests are in progress at the present time The older building also contains the machine sho and galvanizing and welding laboratories, while one floor, occupied by the Development Department, includes an exhibition illustrating the practical results of the Association's researches.

The Association's annual lunch on June 29 was made the occasion for celebrating the completion of the new laboratories, and the large company assembled then proceeded to Euston Street where the building was formally opened by the President of the Board of Trade. Mr. Oliver Stanley also unveiled a memorial to the Association's chairman from 1920 to 1937, the late Mr. Thomas Bolton, to whose leadership the success of the Association has been due in no small measure. The memorial is a cast bronze portrait plaque, fixed on the wall of the entrance hall of the new building.

ASSOCIATION OF TECHNICAL INSTITUTIONS

AT the recent summer meeting of the Association of Technical Institutions, held at Harrogate, papers read included "The Present Position of Technical Education in the West Riding" (by Mr. A. L. Binns, director of education for the West Riding of Yorkshire), "Whither Technical Education?" (by Dr. T. J. Drakeley, principal of the Northern Polytechnic, London), and "Technical and Vocational Education in the U.S.A." (by Mr. G. A. Robinson, principal of the South-East London Technical Institute).

Mr. Binns said the organization of technical education in the West Riding was on a regional basis, he machinery for which is provided by the York-hire Council for Further Education, which is repre-entative of all the authorities for higher education n the area. The scheme, Mr. Binns pointed out, is typical English solution of a problem which might sewhere have been solved by more autocratic ethods. "It aims at combining the advantages of se local interest and initiative with those of a mmon policy over a wide area, and it hopes to cure these advantages by cordial co-operation ong free and independent statutory bodies rather an by a policy of subordination or absorption." ementary technical instruction is provided as close possible to the homes of the students, while the re advanced work is concentrated progressively centres where traffic routes converge. In connexion h the advanced work, financial arrangements ve been made which leave the students free to end the institution they prefer, whether it is hin or without the boundary of a county borough. short, the Yorkshire Council for Further Education works to harmonize the relations between the different local authorities and the industries within the region.

Dr. Drakeley referred, during his paper, to the report on Policy in Technical Education which had been published by the associations dealing with technical education and the National Society of Art Masters. He argued for certain recommendations which he hoped would promote discussion along definite lines and secure, in the words of the above report, that the latter shall produce "not only skilled scientists, technicians and designers, but also persons adaptable to continuous industrial and economic change".

The main point put forward by Dr. Drakeley was that technical education should concern itself immediately with the training of a skilled rank and file for industry and commerce. The training provided in the schools should involve a high degree of craftsmanship, together with a good educational standard. He recommended also, however, that provision should be retained for vertical advancement by the development, where necessary, of senior day technical or trade courses from the age of 16 plus to about 19 plus, such training to lead to the more responsible posts in industry. Speaking of national defence schemes, Dr. Drakeley urged that a fraction of any expenditure on Government or industrial schemes should be set apart for the purpose of training necessary personnel. He also argued that in the development of all technical courses, especially those designed for the training of skilled workers, the active co-operation of employers' and employees' organizations should be obtained.

Mr. G. A. Robinson's paper summarized the formation he had obtained during two visits to the nited States. His first visit was made as Page holar, when he was able to go to certain universities ith faculties of engineering and to examine their partments of industrial administration, in addi- on to ascertaining the progress made by summer hools (technical education) of the Oxford type. On at occasion he visited a few trade and vocational hools, but his main objectives did not lie in that ld. During his second visit, in 1938, he had three jectives, namely, to attend summer schools for cational and other teachers; to attend the Seventh International Congress on Scientific Management, and to renew the technical contacts he had made in 1936. His paper included his comments on universities and institutes, evening instruction, vocational education, industrial economics, apprenticeship, management education and production training. In his conclusion, he suggested that, in vocational education, Great Britain has much to learn from America, "especially under proposed changes in our secondary school system"; in technical education, however, he thinks that America has equally as much to learn from Great Britain in work of the national certificate type and in high-grade craft technology.

CONGRESS OF THE SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES, 1939

THE first Congress of the South-Eastern Union of Scientific Societies held at St. Albans in 1911 howed that the effect of Queen Victoria's raising the wn to the dignity of a city and appointing a bishop d not only resulted in the late Viscount Grimston storing the Abbey of the Benedictine monastery, ected over the Saxon shrine of the first Christian artyr, to the form it took under its abbots; but also irected attention to the excavation of the sites of he three older cities of Verulamium under the perintendence of Dr. and the late Mrs. Mortimer heeler. The second Congress, held this year, during une 6–10, marked a second stage and showed the terest and pride which the present-day citizens, ith their enlarged boundaries and modern buildings, ke in their long history. The Corporation has built fine museum specially to house the Verulamium nds which were arranged by Mr. Philip Corder, the rator, and both he and Dr. Mortimer Wheeler were n the spot to explain and interpret the finds. A isit to the excavated amphitheatre, adapted by the omans as a Greek theatre, is unique in Great ritain, and serves to emphasize the fact that it was he only town given the status of "Municipium", hus making its inhabitants citizens of Rome and erulamium the capital of England, with London erely its port twenty miles away.

The restoration of the Abbey for conversion into cathedral meant the removal of the grammar school, oused in one of the aisles of its very long nave, to site inside the old Abbey Gate, and the modern uildings with a fine school hall and lecture theatre, ogether with the Abbey Institute rooms, served well or the Congress sessions and lectures. As in 1911, he old Town Hall was made available for the recep- ion of members, and here the Mayor (Councillor T. F. Elm) and local patrons welcomed the Congress and heard the presidential address given by Mr. James G. Mann, keeper of the Wallace Collection and now Master of the Armouries at the Tower of London. His subject was "The Changing Conditions in the Study of Art and Antiquity", and dealt mostly with he growth of museums during the last century, pointing out that it was almost entirely due to the nthusiasm of amateur collectors; now there is a isk in paid officials labelling and arranging their pecimens and pictures for the education of students —even classes of school children unable to appreciate artistic treasures—and the true amateur is driven to collect unwanted 'bygones' hitherto neglected by professional curators. Mr. Mann made a plea for retaining works of art in their original setting, and for dispersing to local museums representative specimens, either permanently or by rotation in loan collections, to improve provincial taste, and specializing the general museums even in the metropolis, making some allowance for accretion.

The Archæological Section heard an address on the changing fashions in place and personal names by Mr. L. F. Salzman. The origin of many forms of place names were explained and an examination of old nominal lists, such as the poll tax required, showed that in medieval times "Mary Anne's" were rare, partly because Mary seems to have been reserved for important personages and because it was not the custom to give more than one Christian name to a girl. Although St. George has always been considered the patron saint of England, the name "George" is almost absent before the time of the Hanoverian monarch.

The address to the Botanical Section, by Mr. P. M. Hall, was devoted to a discussion of the dozen hybrid wild orchids of Great Britain. The crosses are far more common in temperate than in tropical vegetation but it often requires microscopic examination to determine the origin of a hybrid. Dr. H. G. Thornton spoke on the investigations, undertaken at Rothamsted Experimental Station, on bacteria in the soil, which are fundamental to the science of agriculture.

Mr. D. Seth-Smith, of the Zoological Gardens, addressed the Zoological Section on "Animal Behaviour". He pointed out that animals brought up in captivity, though they lose the fear of man and depend upon him for food, nevertheless retain in reared generations certain wild habits; he said that zebras are liable to panic, lions crouch on sighting a dog, deer attack familiar attendants and birds fight in nuptial display. Dr. C. B. Williams spoke of the results obtained from 800,000 insects collected in light traps of his design at Rothamsted Experimental Station in four years. The unexpected results show that the majority are Diptera and that Coleoptera rarely come to light, that at 35 feet above ground females are twice as numerous as males but not so at ground-level, that twice as many insects come to light on dark cloudy nights as in clear moonlight, and the separation of catches by hours shows the periods in which various species are active and the effect of change of temperature and barometer upon numbers captured.

Mr. C. P. Chatwin devoted his address to the Geological Section to the "Lost Atlantis", taking the view that Africa was the central land mass from which the continents divided as in Wegener's theory. In both the zoological and geological sections papers were read on modern ideas of the theory of evolution, by Mr. Ward Cutler and Dr. Dighton Thomas respectively.

A new departure at this Congress was the formation of a Section for Social Science, following the lead of the British Association, by adapting the Regional Survey Section to embrace scientific subjects not dealt with by existing sections which may be of special interest in different centres to be visited. Mr. Alexander Farquharson, honorary general secretary of the Union, explained the scheme and introduced various speakers: Miss S. Margery Fry on "Juvenile Delinquency"; Miss Hilda Jennings on "Industrial Transference"; Lord Forrester on his Welsh experiment of solving the problem of the "Older Unemployed Man", and in the public evening lecture he also took the chair for Prof. Winifred Cullis's lecture on "Biology and National Fitness".

Another evening lecture was given by Brevet-Col. W. le Hardy, who is engaged by the Corporation of St. Albans to report on the city charters, which are numerous and afford glimpses of the past history of the city and its importance for teaching the arts and crafts; but history from the charters will require supplementing by delving at the Public Records Office to trace out the activities of the abbots who ruled before the Reformation.

No less than twelve excursions were organized by a most efficient local committee convened by Miss Phyllis Gibbs as the Congress Secretary, a post her father had held in 1911. The general excursion was to Rothamsted Experimental Station and was addressed by Sir John Russell. A tour of the Lawes Trust grounds was made and in the Entomological Department an interesting experiment into the habits of bees was in progress. Bees were mark for identification by spots of cellulose paint emergence and their work in the hive watched age groups. It is here that the records collected the Insect Immigration Committee appointed by t Union are analysed, details of which appeared NATURE of January 5, 1935 (p. 9).

It is the practice of other naturalists' unions in Gre Britain to hold single day congresses at the invit tion of a local society to transact business for mutu co-operation, a practice which is now contemplat as supplementary to the five-day annual Congre of the South-Eastern Union, with the view of keepi in touch with centres too small to house represent tives and members from all the societies, whilst st keeping the representative assembly to the last da of the main Congress. This year, at the forty-fourt assembly, the only controversial matter brought u for discussion was connected with finance. As S Richard Gregory remarked to the Council, it is tradition to be proud of that the Union has been ab to maintain its activity for so long without the ai of a single paid official or any sort of endowmen and the economy of its administration is shown b a total expenditure of only £127 last year and the mainly upon printing, of which costs have more tha doubled in the last twenty years. If only a yearl income of £100 was available from an endowmen or some other outside source, the restriction o printing the transactions *in extenso* in the *South Eastern Naturalist and Antiquary* would disappea Increasing subscriptions is no solution, for it woul only mean cutting off the poorer members it is mos desired to help. With such local interest as wa displayed at St. Albans there is no fear of an actua deficit; but that cannot be expected if the nex Congress is held at Cambridge, where local support i sure to be meagre during the long vacation, howeve important the addresses may be and however muc members may enjoy a visit to a university town s suitable in all other respects.

T. D.

THE LOCUST PROBLEM IN 1937

THE latest survey on the locust problem, by Dr. B. P. Uvarov in collaboration with Miss W. Milnthorpe, has recently been published on the recommendation of the Special Committee on Locust Control appointed by the Economic Advisory Council (H.M. Stationery Office, 3*s.* net). It is gratifying to note that the international co-operation for collecting information relative to locusts continues in an efficient manner. The present survey deals with the locust problem in 1937, and it demonstrates once again the importance of keeping continuous watch over developments in the situation.

The desert locust (*Schistocerca gregaria*) did not give rise to swarms during the period of review either in South Africa or in India. On the other hand, the situation in the Sudanese-Arabian area during the winter of 1937–38 gave rise to anxiety. In the early months of 1938, it was reported as breeding in the gregarious phase in several localities along the western coast of the Red Sea. No evidence of actual swarming has been recorded, and this is evidently due to the success of the control measures that were applied. This hopeful event should well justify the establishment of proper organizations for the purpose o watching those areas known to be areas of swarn production. In this connexion it is mentioned tha preliminary arrangements for such organizations o an international basis are progressing very favourably

As regards the African migratory locust (*Locust migratoria migratorioides*), all the eastern part o Africa remained free from this insect during the firs half of the year under survey. Later in the year however, the situation changed. Swarms appeare in West Africa and spread eastwards, with the result that the Anglo-Egyptian Sudan became reinfeste by this species after an interval of two years. Thi invasion does not, however, appear to be an entirel new outbreak and its origin seems to have been in districts of Oubangui-Chari, and farther to the west, where swarm production has been noted fo the last two or three years.

The red locust (*Nomadacris septemfasciata*) has shown a slow decline in its outbreaks. While there was no marked reduction in the area under infestation, in many instances the swarms were smaller and not so dense.

CIENCE NEWS A CENTURY AGO

atistics of Births, Deaths and Marriages

ON July 8, 1839, *The Times* said: "We have eceived the first annual report of the Registrar-eneral of Births, Deaths and Marriages, in England, resented to both Houses of Parliament by command f His Majesty." From the annual abstracts up to une 30, 1838, *The Times* quoted the following gures: Total number of persons married, according o the rates of the established church 107,201; not ccording to the rites of the established church 11,481. Total of births registered 399,712; total umber of deaths registered 335,956. Discussing ne or two features of the returns *The Times* said: A very marked diversity also appears in the proortion of deaths of infants in different parts of the ountry. In the mining districts of Staffordshire and Shropshire, in Leeds and its suburbs, and in Cambridgeshire, Huntingdonshire and the lowest parts of incolnshire, the deaths of infants under one year have been more than 270 out of 1000 deaths at all ages; while in the northern counties of England, in Wiltshire, Dorsetshire and Devonshire, in Herefordshire and Monmouthshire, and in Wales, the deaths at that age, out of 1000 of all ages, scarcely exceeds 180."

Application of Photography to Astronomy

ON July 10, 1839, John Pringle Nichol (1804–59), professor of astronomy in the University of Glasgow, sent a long letter to the editor of the *Scotsman* dealing with the possibilities of applying photography to scientific observations. It had occurred to several individuals, he said, that photography could be used for recording the readings of meteorological instruments, and he proposed to erect one of the recording instruments of Mr. Jordan, of Falmouth, in the grounds of the new observatory at Glasgow. "The probable and universal application of this subject to my own especial subject are not less important than the foregoing. If, as we cannot now doubt, Daguerre's plates are so sensitive, and if as reported, he has succeeded in obtaining a *trail* from the passing light of the moon, that luminary will unquestionably record a picture of herself, capable of undergoing microscopic scrutiny upon a plate so placed as to receive her image through a large and revolving equatorial". He then went on to refer to the possibility of photographing the spots on the sun. "Obtaining the image of the sun through an adjusted equatorial on a roll of prepared paper, moving after definite intervals of time, the ever-changing disc of that luminary would infallibly write down its own history. As soon as my own equatorial is placed, I shall certainly endeavour to realise this idea when circumstances are favourable". In the following year a few "moon-pictures" one inch in diameter were obtained by means of photography by John William Draper (1811–82), professor of chemistry in the University of New York.

A History of British Zoophytes

THE *Athenæum* of July 13, 1839, contained a notice of Dr. G. Johnston's "A History of British Zoophytes". "A work has been long wanted," the *Athenæum* said, "which while it presented a sketch of the probable affinities of the groups composing the entire class, should furnish materials for a determination of the various marine and lacustrine species that inhabit our coasts or inland waters. . . . The author's own views on classification agree, in the main points, with the arrangement proposed by Milne Edwards, but the systems of Cuvier, Müller, Lamoroux, Blainville and others are placed before the reader . . . the most acceptable portion of the work will be the full and clear descriptions of species, and the numerous and beautiful engravings with which the volume is illustrated."

Dr. G. Johnston (1797–1855) was a medical man in Berwick and was the founder and first president of the Berwickshire Naturalists' Club.

UNIVERSITY EVENTS

BIRMINGHAM.—Prof. B. L. Goodlet, professor of electrical engineering in the University of Cape Town, has been appointed to the chair of electrical engineering rendered vacant by the death of Prof. W. Cramp.

The following gifts are announced: £350 per annum for seven years from Messrs. Rubery Owen, Ltd., of Darlaston, for a research fellowship in zoology; £5,000 from Mr. J. R. Hugh Sumner and £150 a year for seven years from the Birmingham Small Arms Co., Ltd., to found a research fellowship in civil engineering.

EDINBURGH.—At a graduation ceremonial on June 30 the honorary degree of Doctor of Laws was conferred on the following, among others: Mr. Harold B. Butler, warden of Nuffield College, Oxford, formerly director of the International Labour Office; Mr. Frank C. Nicholson, librarian to the University of Edinburgh, 1910–1939; Prof. G. N. Watson, professor of pure mathematics, University of Birmingham; Prof. J. C. Webster, formerly professor of obstetrics and gynæcology, Rush Medical College, University of Chicago.

The degree of Doctor of Science was conferred on the following: K. A. Chowdhury, for a thesis entitled "Growth Rings in Indian Trees"; H. P. Donald, for a thesis entitled "Studies on Growth and Variation in Large Animals"; K. Fuchs, for a thesis entitled "On Some Problems of Condensation Quantum Dynamics and the Stability of Nuclei"; F. B. Hutt, for a thesis entitled "Genetical and Physiological Studies of the Domestic Fowl".

LONDON.—The Senate has resolved that, on the occasion of the celebration of Foundation Day, 1939, titles of the degree of D.Sc. *honoris causa* be conferred on Prof. Niels Bohr and Sir Robert Robinson, and the degree of D.Sc. (Economics) *honoris causa* on Mr. R. G. Hawtrey and Mr. Simon Marks.

The title of reader in inorganic chemistry in the University has been conferred on Dr. H. J. Emeléus, in respect of the post held by him at the Imperial College of Science and Technology.

Prof. R. G. Collingwood, Waynflete professor of metaphysical philosophy in the University of Oxford, has been appointed Creighton Lecturer for the year 1939–40.

The degree of D.Sc. has been awarded to Miss Frances M. L. Sheffield (King's College); Mr. P. V. Sukhatme (University College); Mr. W. S. Stiles, an external student.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Assistant Lecturer in Geology—The Registrar, University, Leeds (July 12).

Assistant Lecturer in Zoology—The Registrar, University, Manchester (July 12).

Scientific Officer in the Air Ministry Research Pool—Under-Secretary of State, Air Ministry (S2A/B.8019), Berkeley Square House, W.1 (quoting B.214) (July 14).

Assistant Mistress to teach Biology and General Science at the County High School, Redditch—The Director of Education, County Education Office, County Buildings, Worcester (July 15).

Junior Scientific Officers in the Metrology Department—The Director, National Physical Laboratory, Teddington (July 17).

Teacher in Engineering Subjects at the Mexborough Schofield Technical Institute—The Secretary to the Managers, Education Office, Mexborough (July 17).

Superintendent of the Branch for Southern Rivers, Freshwater Biological Association, and a **Research Assistant**—The Registrar, University College, Southampton (July 18).

Lecturer in Physics and Chemistry—The Principal, Faraday House, Southampton Row, W.C.1 (July 20).

Research Fellowships in Glass Technology—The Registrar, University, Sheffield (July 21).

Assistant Officers (Civil Engineers) in the Indian Railway Service of Engineers—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (quoting Appointment 1/1A) (July 22).

Professor of Agriculture (Animal Husbandry) in the Canterbury Agricultural College, Lincoln, New Zealand—The Secretary, Universities Bureau of the British Empire, 88a Gower Street, W.C.1 (July 27)

Educational Psychologist—The Director of Education, Education Offices, Philip Lane, Tottenham, N.15 (July 31).

University Readership in Morbid Anatomy at the British Post-graduate Medical School—The Academic Registrar, University of London, Senate House, W.C.1 (September 12).

Professor of Chemistry—The Secretary, University, Aberdeen (September 16).

Two Technical Assistants in Agricultural Economics—The Adviser in Agricultural Economics, King's College, Newcastle-on-Tyne 2.

Geologist in the Geological Survey of the Anglo-Egyptian Sudan—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1.

Inspector of Explosives in the Stores and Ordnance Department of the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1.

THE MUSEUM AND THE SCHOOL

WITH commendable restraint those responsible for the organization of the exhibition of museum publications of educational interest, which was held at University College, London, during June 20–July 15, made no attempt at exhaustive or elaborate display. It was a sampling, for which the material was derived from London and from certain museums of the United States of America. The English contributors included, in addition to the national collections, the London Museum and one of the museums of the London County Council—the Geffrye Museum. Modest as was this effort, it served the purpose, as no doubt was the intention, of provoking thought. The contrast here presented between the methods of the English and the American museums inevitably gave rise to reflection as to the purpose of these great collections of objects of natural, scientific and historic interest, of beauty and of rarity, and the nature of the function which they perform, or might perform, in the life of a community.

As Lord Bledisloe said in his address to the jubilee gathering of the Museums Association, the museum in its original conception was "a fountain of culture alike for young and old, for rich and poor, for layman and expert, adapted to the everyday intellectual and spiritual requirements of the nation as a whole". Without venturing to question the historical accuracy of this statement, we may concur in Lord Bledisloe's dictum and agree with him when he went on to point out, coupling the cinema with the museum, that "as the eye is the most efficacious channel of entry into the mind, there are no more promising educational agents or more powerful stimulants to the imagination than the museum and the cinema". But at the same time, as every educationist is aware, it must not be overlooked that visual impression, whether in adult or child, is but fleeting, unless it finds the mind of the observer already prepared to receive it, and able to link it to material which the mind has already made its own. It is by the nature and the extent of the museum's co-operation with the observer in storing up such a body of assimilated fact that the performance of its educational function must be judged.

In all the important London museums and collections, the institution of guide-lecturers, of special exhibitions, permanent or temporary, illustrating some special phase or problem, and a ready hospitality extended to school visits, have done much to make the public familiar with the character and meaning of the objects in these collections. The services of the lecturers, however, are available for comparatively few of the museum's visitors—those who have the leisure and the opportunity to attend at stated times. For the majority, or at any rate a large proportion, more intimate and more intensive study than is possible in a perambulation of the galleries, even the occasion for arousing interest and stimulating study, must depend to a great extent upon the museum publications. Within the limited space of the exhibition room at University College has been shown a selection of these publications. It was headed by some of the attractive and sometimes striking posters directing attention to the collections in the various museums, which are displayed by the London Passenger Transport Board. Each of these posters, artistic and brightly, but not garishly, coloured, is characteristic of the collection which it announces. The second, an extensive exhibit, consisted of the long range of picture post-cards and reproductions, mostly in colour, which illustrate almost every branch of science, art and history susceptible of demonstration in a museum.

Of the museum publications in book form, the more technical and advanced did not come within the scope of an exhibition intended to consider only the needs of schools, and the selection shown was confined to the simpler and more popular guides, which do, in fact, carry further the interest aroused by the collections themselves, or by the post-card series. Such a development of interest is to be noted, for example, in the Science Museum series, dealing with topics such as the development of transport, locomotion, navigation, aeronautics and the like.

Reviewing the exhibits from the English museums as a whole, and as an instrument of instruction, the more striking features are the care which has been lavished on the selection and preparation of the various series, the care in production and reproduction, and the scholarship and knowledge which have been drawn upon freely to make known to the general public the character and meaning—scientific, æsthetic or historical—of the wealth of objects displayed in London's museums. It must be apparent, however, that in so far as this material was brought together to illustrate the educational interest of museum publications, it shows strikingly little effort to make readily available for the school a vast amount of material of immense educational value. Except for the Geffrye Museum, which, with the Horniman Museum at Forest Hill, is part of London's educational organization, there is no direct orientation towards the needs of the school. It is here that the contrast with the American museum becomes marked.

Exhibits were shown from five of the larger American museums: the Metropolitan Museum of New York, Boston Museum of Fine Arts and the Brooklyn, Buffalo and Cleveland Museums. It is made abundantly evident that each of these museums regards itself, even if this be not explicitly stated in the terms of its foundation, as having a specific function in the cultural life and educational system of the region in which it stands. Normally, it has an educational division, section or committee, and an educational staff; and it undertakes organized educational work. There is a carefully prepared system of preparatory propaganda. Post-cards, memoranda, and programmes are circulated among the heads of primary, secondary and technical schools an other educational institutions. In some museum courses are specially arranged to fit in with th curricula, after consultation with the staffs c primary, secondary, and technical schools. The are given by members of the museum staff i special rooms. The museum educational sta is available for consultation by teachers an others interested in education, sometimes at small fee.

Finally, there are the museum publications usually a museum journal, which, in addition t notes on recent acquisitions, will contain articles o special groups of exhibits; or, in those museum which specialize in art, dealing with the work of a painter or sculptor, or like topic of artistic o antiquarian interest; while some museums publish a periodical devoted entirely to the interests o school children, and dealing with Nature studies, hobbies and the like. Of a more specifically educational character are sheets or cards of grouped illustrative material, with notes prepared by the museum staff. These are circulated for instructional purposes among the schools. There are also special publications, usually in pamphlet form, or guides dealing with grouped exhibits or special collections.

In general, it may be said that the material which is thus circulated among the schools or made available for their use is scarcely comparable in its printing or general technical character with the publications of English museums, nor, it may be said without offence, does it show the same standard of scholarship. At the same time, it has to be admitted that, having been prepared for a specific purpose and with the educational end in view, it is more certain to reach its mark.

It was abundantly apparent in the material shown at University College that the American museum has not shrunk from taking what it has regarded as its educational responsibility very seriously. This is due in part, of course, to the fact that, whereas the British national and other important collections, owing to their origin, have assumed the character of storehouses of national treasures, and their connexion with the advancement of knowledge has been almost entirely by way of research and not of instruction, in the United States the museums have been founded as, or have become, part of the cultural equipment of the region each serves. Most of them, too, are dependent for their current expenses, not on their ndowment or on support from public funds, but n fees and membership subscriptions; the xtent of membership is reflected by the degree in hich the activities of the museum meet the ultural needs of its area.

The English institution more nearly comparable ith the American museum is the local provincial museum, which grew out of the interests of the ocal literary, philosophical or antiquarian society. When communications were less easy and other istractions less numerous than they are now, this erved as a social and cultural focus for its neighourhood. Its educational function might well be evived, where it has lapsed, and extended.

While the very different conditions which affect ur large museums, in contrast with those affecting American museums, must be recognized, yet a omparison of the two systems of organization in Great Britain and in the United States gives rise o an uneasy feeling that the most is not made n education of the wealth of scientific and cultural material that is available in collections in Great Britain. If it be pointed out in extenuation that a remarkable range of illustrative material from which to select is available for the teacher, the reply surely must be that the teacher is not a specialist; and simple and even elementary as much of the detail in the museum guides and other publications may seem to the specialist, for the layman, however intelligent, they make stiff and uphill reading. The classes and lectures for teachers at the Horniman Museum, and the appointment of liaison officers between school and museum on the inspectorate of the London County Council, were steps in the right direction; but they do not go far enough. To be of lasting value, museum material must be brought into intimate relation with the school curriculum. Intermittent visits to general collections have little permanent instructional value. To suggest that special exhibitions should be arranged in special rooms to meet the needs of schools raises a problem with too many ramifications for discussion here. In the provincial museum, however, education might provide a channel for the further assistance from public funds for which a plea has been put forward. Such matters will no doubt come within the purview of the promised public inquiry.

FUNDAMENTAL CONCEPTS OF ELECTROMAGNETICS

Electromagnetics
A Discussion of Fundamentals. By Prof. Alfred O'Rahilly. Pp. xii + 884. (London, New York and Toronto: Longmans, Green and Co., Ltd.; Cork: Cork University Press, 1938.) 42*s*. net.

HOWEVER gratifying the remarkably rapid progress of experimental science and its practical applications during the last few decades may appear, the immense accumulation of new facts and hypotheses has tended greatly to confuse rather than to elucidate our fundamental concepts, and the edifice of science is becoming like a Tower of Babel in which hosts of skilled workers are busily engaged on their several portions but without plan or architect, and are becoming so divided by specialization as scarcely to be able to understand one another. To such an extent has this confusion grown that we seem to be reverting to pre-Newtonian scholasticism, and many modern men of science are now adopting the speculative and metaphysical modes of thought and expression against which science had to struggle for its very existence in its infancy; so that although humanity is more and more amazed at the achievements of science, it is losing confidence in it as a trustworthy interpreter of natural phenomena and as a guide to human progress.

There is therefore urgent need for a comprehensive review of our fundamental concepts, and Prof. O'Rahilly deserves our cordial thanks and admiration for the energy, skill, and courage with which he has undertaken this formidable task. Within the space available for this review, it is impossible to do more than indicate the immense field covered in this large volume, one of the most interesting and valuable features of which is the collection of quotations from the greatest authorities which reveal the large divergences of opinion which have always existed between them, even when agreement on most fundamental principles was supposed to prevail.

The majority of students, at least in Great Britain, have been brought up on the Maxwellian theory, involving the Faraday concepts of electric and magnetic fields in a medium, and are now being converted to the doctrine of relativity; but the author reminds us of the great body of theory built up by the Continental physicists, Poisson, Gauss, Ampère, Neumann, Riemann, Weber and Lorenz, and their successors, Voight, Liénard, Schwarzschild and Ritz, based on action at a distance between discrete charges and the assumption first made by Riemann in 1858 of a finite velocity of propagation approximating to that of light. He points out that not only did they arrive at results in accordance with those derived from the Maxwellian equations, but also that they were anticipatory of the modern electron theory, and therefore more in accord with recent experimental developments. The Maxwellian concept of electric displacement in space, involving a basic medium or ether, was greatly disliked by Continental physicists, and only secured their assent for a short period after Hertz's brilliant experimental verification of Maxwell's theory of electromagnetic propagation; so that the discovery of the electron and the rapid advance of corpuscular physics provided a welcome excuse for reversion to their earlier ideas.

As the author is professor of mathematical physics at University College, Cork, the volume is naturally highly mathematical; but readers with very little mathematical ability will find the discussion of various theories and the conflicting views of high authorities most interesting and thought-provoking—so much so that it may lead someone to suggest a new fundamental hypothesis which will at last satisfy not only quantitative but also intellectual needs. The very fact, as is clearly demonstrated in the volume, that widely divergent fundamental concepts may lead to almost identical formulæ which give close quantitative agreement with experimental measurements, shows that such quantitative agreement is no proof of the validity of the concepts; so that mathematical reasoning must be supplemented by physical insight.

Only two physical hypotheses at present hold the field: (1) the emission, or what the author calls the ballistic, hypothesis, which was definitely adopted by Ritz; and (2) that of a medium, adopted by Faraday and Maxwell; since the old action-at-a-distance theories and the modern doctrine of relativity have been concerned only with obtaining quantitatively accurate general formulæ, regardless of any agency by which bodies or charges act upon one another. In this the latter resemble Newton's theory of gravitation, but although Newton expressly refused to promulgate any hypothesis, he emphatically stated that the idea "that one body may act upon another at a distance through a vacuum without the mediation of anything else by and through which their action and force may be conveyed from one to another—is to me so great an absurdity that I believe no man who has in philosophical matters a competent faculty of thinking can ever fall into it". This certainly expresses the feeling of every physicist who does not accept the dictum that mathematical formulæ represent the only true reality, and th belief in and search after the mediating agency bound to persist.

Prof. O'Rahilly, while accepting the validity Maxwell's equations and the existence of an ethe has definitely discarded the concepts of electric an magnetic fields, and takes his stand on the Liénard Schwarzschild force formula, which appears to b equivalent to the simple vector formula given b the present writer in NATURE of December 3, 193 except that the former contains a factor of ½ i the third term, which seems to conflict with th Neumann inductance formula, and two addition second order terms in v^2/c^2 derived from th assumption that longitudinal forces are also pro pagated with the velocity of light. This scarcel seems consistent with the deduction from th energy of a moving electric field that its inertia only of a transverse character, but the autho claims that these terms are necessary for reconcilin the formula with experiment.

In spite of his own mathematical powers, Prof O'Rahilly is far from over-estimating the value o mathematics; and his comments on some of th most elementary mathematical concepts, includin dimensions, as well as on the modern ideas o space-time, are interesting and amusing. In orde to avoid the prejudice against the concept o 'absolute' motions, he has adopted the Greek wor *schesis* for a basic framework; and he claims tha the only truly consistent relativistic theory wa the ballistic or corpuscular theory of Ritz, an that the modern doctrine of relativity is funda mentally schesic. That he is justified in thi claim seems clear from the constant recurrence o the term v^2/c^2 in the Lorentz transformatio formula (which the author points out was enun ciated by Voight in 1887) and so many relativisti formulæ, which term, like the v and v^2 in th Liénard–Schwarzschild force formula, can have n meaning unless such a framework or schesis i implicitly assumed.

Although probably every reader of this volum will find himself alternating between heart agreement and strong disagreement with Prof O'Rahilly's various criticisms and conclusions, hi wide outlook and critical survey of the variou theories entitle his views to respectful consideration. Whether they are justified or not must be left for the future to decide, but we can heartily endorse Prof. Conway's concluding remark in the foreword, that the volume "is more than a review of existing knowledge, it is a courageous attempt at reconstruction; and if we do not always agree with the writer, he certainly makes us reflect. I recommend this book to every serious student of Electromagnetics".

C. V. DRYSDALE.

CHEMICAL REACTION IN THE ELECTRIC DISCHARGE

The Electrochemistry of Gases and other Dielectrics
By Prof. G. Glockler and Prof. S. C. Lind. Pp. xiii+469. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 30*s*. net.

THE appearance of this first book on the electrochemistry of gases will be welcomed by a wide circle of physicists and chemists, who will also remember that one of the authors has written the first book on a related subject, namely, reactions initiated by α-particles. This book is the more welcome because of all the chemical writers on electrochemistry, none since Löb in 1905 appears to have found the part of the subject relating to gases of sufficient importance to devote to it more than a trivial portion of a book, despite the very extensive literature on the subject. Physicists writing on discharge phenomena, with the exception of Stark in 1902, are even more disappointing, for all the later writers have either omitted to mention the subject or dismissed it in a few lines.

The book was written at the request of the Committee of Electrical Insulation of the American National Research Council, and attempts to cover the field "considering all forms of electrical discharge and all types of reactions"; it contains, however, no more than three pages relating to industrial applications, vitamins, insulation, and lubricating oils.

There are three main sections in the book. Part 1 is entitled "Typical Reactions in Various Forms of Discharges"; its theme is illustrated in 139 pages by what the authors describe as a "quite arbitrary" selection of reactions which have been examined in one or more of the known types of discharge, including slow and fast electron beams. The last section is devoted to an account of the properties of molecular fragments as observed *outside* the discharge in which they are formed.

Part 2 deals in 190 pages with "Chemical Reactions in Electrical Discharges" and attempts to cite "most of the reactions that have been studied", which claim for the most part is well substantiated. The formidable task of arranging the very heterogeneous material from some 656 references in this section alone has been dealt with by considering the reactants in ascending order of atomic weight; in some cases, this has led to the dissemination of the information concerning the formation and decomposition of a given substance through several chapters.

Part 3 is entitled the "Physical and Theoretical Aspects of Discharge Reactions". The first three chapters deal with electron affinity, ion mobility, and a list of the ions observed in discharges. Then follow two interesting chapters on ionization produced by reaction, and on sputtering. The book closes with a chapter on the mechanism of discharge reaction.

Considered as a whole, the great value of this book derives from the fulfilment of the authors' aim to compile the vast mass of experimental data so as to facilitate the comparison of the various forms of discharge reaction, both amongst themselves, and with reaction initiated in the same systems by other agencies. This will be invaluable to all investigators of discharge phenomena, whether chemists, physicists or engineers. It should be a powerful stimulant to further exploration of the field, both experimentally and theoretically; and it may be that even the industrialist will be attracted to consider the possibilities of some of the remarkable syntheses that are described. It is, however, difficult not to feel a slight and perhaps ungracious sense of regret that, having such familiarity with this enormous collection of information, the authors have not essayed a more critical commentary on the relative value of their material.

Only fourteen pages are allotted specifically to the chapter on the mechanism of reaction, although most of the attempts to formulate a theory are mentioned either there or elsewhere in the book. The accounts of the various theories are, however, rather uneven; for example, Kirby's quantitative theory of positive column reaction is barely mentioned, whilst much of Warburg's work is given in detail. The authors themselves have chosen to discuss reaction mainly in terms of the ion cluster theory for reasons of "simplicity and personal acquaintance". The statistical approach to the quantitative theory of discharge reaction is, however, a little surprisingly dismissed without even formal statement, for the unproved and possibly irrelevant reason that it is impossible in this way to explain certain facts concerning reactions initiated along α-particle tracks.

The book is beautifully produced, readable, and illustrated with numerous clear diagrams; there are good author and subject indexes.

R. Winstanley Lunt.

GENETICS IN THE GARDEN

The Genetics of Garden Plants
By M. B. Crane and W. J. C. Lawrence. Second edition. Pp. xxi+287. (London: Macmillan and Co., Ltd., 1938.) 12*s*. 6*d*. net.

THAT a second edition of this work should have been called for within four years of the appearance of the first shows that it has met a definite need. Nor is this surprising; for the dimensions to which the study of scientific plant breeding has attained offer one of the most spectacular examples of the rapid rise of an applied science based upon a simple initial discovery.

It is not much more than thirty years ago that Biffen declared plant breeding to be a game of chance with the odds on the plant. To-day, thousands of plant breeders all over the world are in a position to define their aim and to pursue it with every prospect of success. The majority of these are, of course, dealing with farm crops of fundamental importance to mankind—with cereals, grasses, cotton and the like—crops where even a very small improvement in quality or quantity is enormously magnified by the vast acreages involved. With this aspect the authors are not concerned. They have confined themselves to the products of the flower and vegetable garden, with the inclusion of fruit trees.

A brief and clear introduction to the principles of genetics and cytology involved is followed by three interesting chapters on flowers and vegetables. Special attention has been paid to such species as have been more intensively studied—to the sweet pea, the stock, the dahlia and the primula, and among vegetables to the tomato, the potato and the garden pea. The matter is presented in a form which allows the reader to obtain an idea of the successive changes that have occurred under continuous cultivation, while at the same time he given an insight into the chemistry of flower colou and brought to realize the importance of polyploidy as a factor in connexion with 'improvement'.

A considerable part of the book is devoted t fruit trees and bush fruit, and is largely base upon the well-known experimental work carrie out at the John Innes Horticultural Institution b the senior author. The genetical analyses of th more important cultivated forms are followed b illuminating discussions on bud sports, sterility and incompatibility—topics all important for the grower of fruit. The final chapter, on the origin of new and improved varieties, should prove o deep interest alike to the student of evolution and to the practical grower. The recently discovered colchicine treatment for the induction of polyploidy is alluded to, perhaps too briefly in view of its extraordinary promise. Doubtless the authors will tell us more about it in their next edition when more data are available. It is suggested also that they might give some account of the work with X-rays and radium which is leading to the production of interesting novelties in various plants to-day.

Altogether this is a most interesting and valuable book, excellently produced and illustrated. To the practical grower its value is obvious, and nowhere else will he find so clear an exposition of the principles underlying his craft. It should make an even wider appeal to the amateur horticulturist who is not merely content to admire the beauty of the plants he grows, but wishes to learn something of their nature and of the causes that have brought them into being.

THEORIES OF VISION AND HEARING

Theories of Sensation
By Dr. A. F. Rawdon-Smith. (Cambridge Biological Studies.) Pp. xiii+137. (Cambridge: At the University Press, 1938.) 10*s*. 6*d*. net.

THIS excellent book deals with sight and hearing and does not include any reference to touch, taste and smell. Dr. Rawdon-Smith gives the reason for this in his introduction. He writes, "It would be safe to say that no theory of general sensibility has yet been proposed which is able to describe the available data. . . . We may note in the fields of olfaction and gustation not that the theoretical position is insecure, but simply that no theoretical position exists."

The four chapters on vision refer to the following subjects: Chapter i to the formation of the retinal image; Helmholtz's theory of accommodation and the pupil reflexes. Chapter ii alludes to the duplicity theory of von Kries, the Purkinje phenomenon, the photochemical properties of visual purple, dark adaptation and night-blindness. Chapter iii refers to the discrimination of intensity, the critical fusion frequency, the acuity of the eye at different nt intensities, the size of the foveal cones, vernier uity, the frequency of the impulses in the optic rve and the various theories of visual acuity. apter iv contains an account of colour vision, brightness of the spectrum, colour mixture, lour-blindness, the choice of primary colours, nultaneous and successive contrast.

Commenting on these first four chapters, apters i and ii are introductory to the ones ich follow. Chapter iii is specially good and ves a very clear picture of the rival theories of sual acuity. The position is made interesting d understandable. Chapter iv contains a good count of the theories of colour perception.

Turning now to the ear. Chapter v deals with e anatomy of the ear : the production of summa- on and difference tones, the functions of the ossi- lar muscles, the cochlea, the organ of Corti, the ode of stimulation of the hair cells. Chapter vi ntains an account of Helmholtz's resonance eory and also of the theories of Ewald and Boring, perimental deafness in animals and boiler- aker's deafness in man, the evidence of models, e evidence of the phase-change beat, the inten- iveness of the ear to the relative phases of tones, the Wever Bray phenomenon, the volley theory, the perception of pitch, the rate of conduction of the auditory nerve fibres, the cochlear response and the auditory tract potentials for a change of phase. Chapter vii deals with methods of producing changes of intensity, the sensitivity of the ear to intensity differences, the sensitivity of the cochlear response to intensity differences, and the probable way that differences of intensity are conveyed to the brain.

The reviewer's opinion on these chapters may be briefly explained as follows : Chapter v gives a good introduction to a description of the functions of the ear. Chapters vi and vii state clearly, and in a manner which is easily understood, the present position with regard to the resonance theory, the volley theory and the Wever and Bray phenomenon, and a number of other points which are very intimately connected with the physiology of hearing.

The book is an extremely successful attempt at epitomizing the very varied theories of vision and hearing, and for that reason alone should be read by all who are interested in the mechanisms of sight and sound.

H. Hartridge.

THE CULTURE OF ORGANS IN VITRO

he Culture of Organs
y Alexis Carrel and Charles A. Lindberg. Pp. ix + 222 + 38 plates. (London : Hamish Hamil- n, Ltd., 1938.) 18s.

THE Carrel-Lindberg perfusion method represents one of the most important technical dvances in biology which has been made in ecent years, so that the present volume, in which he authors describe in detail their apparatus, its ode of operation and the experimental results btained up to date, is extremely welcome.

The apparatus is designed to maintain a sterile, ulsating circulation of nutritive fluid through solated organs. It consists of two main parts : he perfusion pump, which contains the organ and erfusion fluid, and a mechanism for creating and ransmitting a pulsating gas pressure to the fluid n the pump. The mechanical details of the pparatus are complicated, but are clearly described nd profusely illustrated with good diagrams and hotographs.

Many culture media have been tried and are rouped into two main classes : natural and rtificial. The former consist of blood serum iluted with Tyrode's solution, to which may be dded such substances as Witte's peptone, insulin, aemoglobin, etc., while the latter, which vary widely in composition, contain either no serum or only a small proportion. In order to detect changes in pH during the course of the experiment, phenol red is always added to the perfusing media.

One chapter is devoted to the preparation of the tissue to be perfused. "The goal of the technique is to transplant an organ into the organ chamber without any damage to its blood vessels and without infection", a goal which demands scrupulously aseptic precautions and no small surgical skill. When the organ has been suitably prepared, it is inserted into the organ chamber and the blood vessels are connected with the perfusion pump by a system of canulæ. The entire apparatus is then placed in the incubator.

One of the major difficulties of the method is to maintain asepsis, which is rendered unusually difficult by the large volume of the tissue and perfusion fluid, by the complexity of the apparatus and by the extensive manipulation involved. Rigid aseptic and antiseptic measures are therefore necessary.

Many different organs and structures have now been successfully perfused for periods up to forty days, and a comparative study has been made of the effects of different natural and artificial media on the histology and functional activity of the organs. "Thyroid glands, ovaries, hearts, kidneys and pancreas were found to maintain or to modify *in vitro* their functional activity according to the chemical composition of the perfusing medium." For example, the addition to the Tyrode solution of only 5 per cent serum allowed parts of the thyroid to survive for several days, the addition of 10 per cent kept the gland alive and almost unchanged for more than a week, whilst 80 per cent produced hyperactivity of the organ as compared with the uncultivated control from the same animal. The thyroid was maintained in a healthy state for several weeks by transferring it every week to another pump with a fresh supply of diluted serum. The photomicrographs of sections of perfused organs present convincing evidence of the healthiness of the tissue even after prolonged cultivation.

Normal functioning of the perfused organs has also been demonstrated. Thus iodine is secreted into the perfusion fluid of the thyroid, and the secretion can be increased by adding thyrotropic hormone to the fluid. Similarly, the perfu pancreas has been shown to secrete insulin.

The number of problems to which this ingeni method can be applied is almost unlimited, a it is to be hoped that the Carrel–Lindberg techni will be introduced into many physiological a medical laboratories. The chief obstacles to more general use are its difficulty and the co plexity of the apparatus required. Dr. Ca encourages the reader by assuring him that method is not so difficult as it looks, but adm that it cannot be learned from a book; it sho be studied in a laboratory where it is be practised.

This book should be of the utmost value to beginner who, having acquired the techniq under expert guidance, is endeavouring to establ it in his own laboratory. Moreover, althou primarily a technical work, it contains matter considerable biological interest and can theref be recommended to the general scientific read

H. B. F

THE LEPCHAS OF SIKKIM

Himalayan Village: an Account of the Lepchas of Sikkim. By Geoffrey Gorer. Pp. 510+32 plates. (London: Michael Joseph, Ltd., 1938.) 25*s*. net.

MR. GORER, who had already proved his mettle as an observer in "Africa Dances", is now, as Prof. Hutton points out in his introduction to this book, a recruit to the ranks of serious anthropologists. He is fortunate in that his first essay in ethnographical study deals with a people, the Lepchas of Sikkim, whose country hitherto has been virtually closed to Europeans. In 1936 he accompanied Major C. J. Morris to Sikkim, and after two months spent at Kalumpong in study of the language, settled with him, under favour of the Maharajah and with his approval as their passport, in the village of Lingthem, which comprises a population of one hundred and seventy-six individuals. Mr. Gorer's book, and the account of the same village published recently by Major Morris, thus give from two different points of view what in sum is a comprehensive picture of a country and a culture, which though changing, up to now have been completely outside European influence and contact.

The author has treated his subject-matter from three different points of view, to each of which he devotes a section of his book. In the first he deals with the material and formalized aspects of Lepcha society—its framework; in the second he cov the mainly unformalized aspects of their life; a in the third he presents the life-history of certa individuals who, it is to be presumed, may regarded as typical.

Certain aspects of Lepcha life have impress him more strongly than others as characteristi and it is under discussion of these in his attemp at their evaluation that the author makes, apa from his purely descriptive work, his main co tribution to anthropological thought—a contrib tion which gives his book an additional claim the serious attention of the anthropologist. these characteristics one is the remarkable la of aggressiveness in the Lepcha character. H explanation which attributes this lack to th swamping of personality in the group feeling discussed by Prof. Hutton in his introduction wi some reserve, but not unsympathetically.

A further characteristic, to which the auth makes extended reference, is the obsession of th whole community by sex, a point which als impressed Major Morris. Here again Prof. Hutto has raised an interesting question by askin whether decline of population and sterility a cause, or effect, of this obsession.

Finally, there is the cynical attitude of th Lepchas to their own religious beliefs, associate with an optimism which is qualified by a complet lack of belief in their own efforts and their future

BUSH FIRES IN VICTORIA

THE drought of the early summer, which affected all south and south-eastern Australia, as followed by a heat wave in the first fortnight January which reached sufficient intensity to duce leaf litter in the forest to tinder dryness. he usual firing by cattle graziers had been in rogress for some months over all the ugh mountain grazing land which lies the north of the prime forest belt. orthern and north-western winds of eat force set in during the first week of anuary and fanned the sporadic fires into onflagrations which swept the country herever forest existed and also much of he cleared grass lands where the stock ad left enough herbage to carry a fire.

Forest losses were severe in New South Wales, and in the Australian capital erritory 3,600 acres were burnt; this epresents a quarter of its plantation area. South Australia suffered also, but proortionately less, for her plantations are ot exposed to the same external fire azard. Tasmania escaped at the time hat the fires were at their worst on the mainland, but towards the end of January and early February, serious fires broke out in that State and severe losses were sustained.

The greatest losses occurred in Victoria, where by the end of that first fortnight of January 5,038,600 acres of forest were burnt over, sixty-seven saw mills and approximately six hundred houses and cottages were destroyed and seventy-one persons lost their lives. The full extent of the loss in timber cannot be gauged, but the amount in the easily accessible areas has been assessed, and this reaches the alarming total of 2,070,000,000 superficial feet in the round. It is estimated that 916,000,000 superficial feet of this killed timber can be salvaged. The dead timber in less accessible areas of burnt ash and alpine ash forest cannot be salvaged.

Victoria's loss amounts to a national disaster, for the chairman of the Forests Commission, speaking at a representative meeting of timber men last year, stated that supplies of ash timber would last less than twenty years.

It will be seen that already the overcutting of the forests had brought the industry to the point where future supplies of logs were becoming a very serious matter, and now the greater part of the timber has been destroyed by fire. Victoria's loss is so severe that it is difficult to see how the industry can fail to sink into insignificance once the salvaged timber has been converted. Investigations are now being made to see whether it is possible to prolong the period of utilizing burnt logs. It is a question of preventing fungus attack, and is therefore a difficult matter.

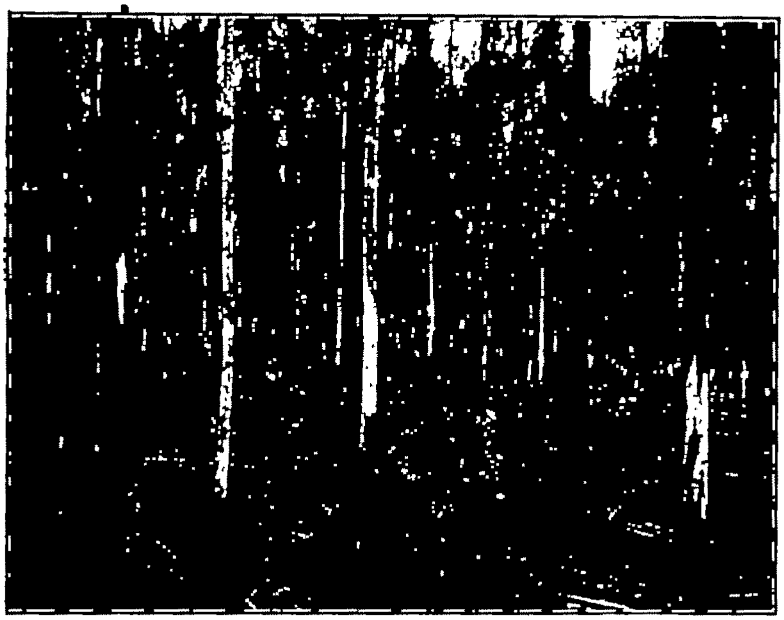
Fig. 1.

VIRGIN MOUNTAIN ASH FOREST, CUMBERLAND VALLEY, VICTORIA.

The genus *Eucalyptus*—the gum tree—of which all the burnt forests consist, is in the majority of cases difficult to kill outright. After a very severe fire has passed through, burning all the crowns, epicormic branches spring from branch and bole and restore the leaf area, and so life is maintained and the greedy branches on the limbs grow into mature branches, new crowns are formed and the greedy branches on the boles fall off. A month after such a fire as has been experienced, the bush



[*Photo: W. Russell Grimwade*

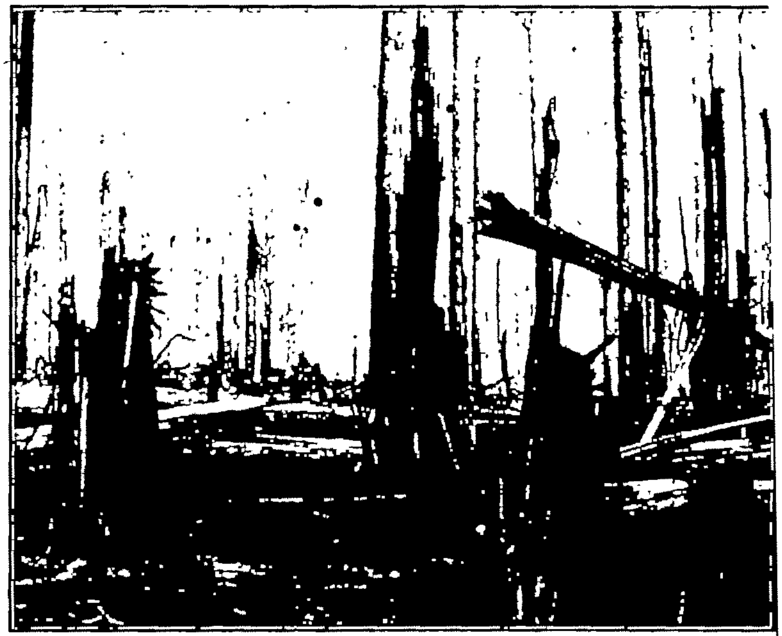
Fig. 2.

NATURAL REGENERATION OF ASH AT NOODJEE, VICTORIA, FOLLOWING THE 1926 FIRE.

is sprouting with green tufts of leaves except—and this is what makes Victoria's case so serious—the species composing the forest belonging to the ash group of gum trees. These are *Eucalyptus regnans*, mountain ash, and *Eucalyptus gigantea*, alpine ash; there are three others, but they are not of the same milling value. These ashes do not renew their leaf surface by means of epicormics and so are killed outright by any fire which attains such an intensity as to burn the crowns. A great part of the Victorian forests consists of these ashes, and the bulk of the sawn timber of that State is ash. Fig. 1 shows a type of forest of mountain ash before the fire. The trees attain heights of more than three hundred feet, and the volume per acre on first quality sites is only beaten by such forests as virgin Douglas fir. So while in the coastal regions of New South Wales great conflagrations took place at the same time as the ash forests were being destroyed in Victoria, the trees will recover, and though greatly injured and yielding as they will inferior products, will reform a forest and perpetuate it.

In the ash belts of Victoria the only hope is that sufficient seed will have been shed from the capsul on the burnt trees, some of whi will not have been consumed a would at that time of the year ripe but closed and would op after the fire had passed b Experience of past fires h shown that a very fine regener tion of ash follows an intense fir The seed falls on a good seed b and has an even chance with a weed growth that springs up i the ashes. Some of the be regeneration of mountain as has occurred in this way. Fig. Noodjee forest, shows what ma be expected twelve years after very bad fire. The big log on th ground was a tree killed in th conflagration that wiped out th forest in 1926; the seed wa shed, good rains occurred an the excellent regrowth, which th Forests Commission has carefull thinned, resulted.

All then is not lost if the trees in the forests though killed, are capable of still reproducin themselves. It means a long wait, for on presen knowledge it takes sixty to eighty years to mak a mill log. That is not all, for during this lon period there is serious danger that an uncontrollable fire will sweep the forest again. This is wha



[*Photo: Forest Commission*

Fig. 3.

WIND AND FIRE DAMAGE IN MOUNTAIN ASH STAND, TANJIL RIVER, VICTORIA, JANUARY 1939.

s occurred in many parts of Victoria, including e fine regrowth shown in the picture. What ppens then is complete destruction, for the ung trees forming the regrowth are too young bear seed and there are no old seed trees to help, d so the forest becomes bracken land, which n only be reforested by planting—a very exnsive business at Australian rates of wages.

Fig. 3 shows the effect of fire on good regrowth. e Forests Commission has been engaged in tendg those fine areas of regrowth and in protecting em from fires. Last year, some £600,000 were ent by the Commission on such work, and fires ve wiped out the greater part of the asset. uch of the money has gone into roads and perment improvements of a capital nature and their lue will remain if the forests are regrown and otected from fire.

This brings up the question: Are these fires evitable? If the answer is yes, then to spend ore money on forestry in Victoria is not justified. here is no doubt that periods of intense dryness, ccompanied by high winds, recur at comparavely short intervals. They vary in degree, but o much credence should not be given to the tatements that have been published that January 939 was the worst ever experienced since white ettlement of Victoria. Well-equipped meteorogical stations are still uncommon in the country istricts, and the evidence of old inhabitants is otoriously unreliable in all matters; degrees f heat and strength of wind are not phenomena apable of easy estimate. Probability points to ntense fire conditions having occurred many times nd likely to recur at least five times in the rotation f an ash forest.

This being so, how is it that there are any ash orests at all? The tree is killed by a severe fire nd the regrowth can scarcely escape destruction ith such a periodicity of five years. The fact hat virgin forests existed up to the recent fire n Victoria is evidence that catastrophic fires did ot occur before white settlement. The trees of he virgin forest are far older than the settlement f Australia, and apart from this evidence there re several facts which make it quite certain that he black man's fires were of small nature. The ate Sir Baldwin Spencer, discussing this matter with the writer, said that the aboriginal only burnt o provide fresh grass to attract kangaroo and wallaby and, owing to his primitive weapons, his aim was to burn very small areas which the clan ould surround when the marsupials were feeding. It is probable that no fires were lit for this purpose in the virgin ash forest because to start a fire in such forests would be difficult and the results would not be so successful for the aboriginals as in the grassed savannah forests adjoining.

It is clear that fires have increased in intensity since white men began to develop Victoria. The early history is interesting in this regard, for it shows what difficulties were encountered by the settlers who were given country to open in the ash belt. They found it most difficult to get a 'good burn' after they had felled the timber. It was only when many holes had been carved out of the forest and a very dry period occurred that a sufficient 'face' of fire was established to sweep through the green forest.

It was not until 1851 that a great conflagration was lighted, and this was so unusual and the results so devastating, that it is known to-day as "Black Thursday, the Day of Terror". Since then, fires of great intensity have occurred at intervals which have become shorter.

The great fires run as follows: 1851, 1898, 1926, 1932, 1939, and of these, the last was only the most serious because of the greater loss of life owing to the country being more opened up and, in consequence, more peopled. The evidence is quite clear that the effect of settlement has been to increase the fire hazard enormously and that forests which were once practically immune from fire became first vulnerable as the face of the conflagration increased and were finally burnt through. The opening up of virgin forest by logging operations contributed largely to the vulnerability of the forests, and the fire prevention organization of the Forests Commission, while adequate to deal with all fires that broke out within the forest reserves, found itself impotent against the raging fires which swept in from Crown lands outside.

After the disasters of 1926 and 1932, fire legislation was tightened up, and to-day the fire prevention laws of Victoria are sufficiently stringent, if enforced, to make fire setting a very risky business in any accessible part of the forests.

The education of the public has been developed to an extent which ensures that everyone is warned against the careless use of fires. The meteorological service sends out through the broadcasting network warnings when the temperature and evaporation are reaching dangerous levels. Roads, tracks and breaks have been cut through the forest and aerial patrols report the outbreak of any fire. Every year by notice in the *Victorian Government Gazette* all areas of land subject to fire hazard are proclaimed as coming under the bush fire laws. These areas cover all Victoria except the inland Mallee country. All these laws and precautions and all this propaganda did not save the position in January. The Government appointed a Royal Commission to inquire into the causes and effects of that fire and to recommend remedies; its report is not yet published so the matter is still *sub judice*. Comment must, therefore, be restricted.

It is quite clear that no internal organization within forest areas can prevent a repetition of the disaster of January 1939. The only way to prevent it is to give the Forestry Commission of Victoria, not only the legal power, but also the departmental machinery and equipment to control fires in the open Crown land leased to graziers beyond the boundaries of the forest reserves. How wide a protection belt is needed must depend on the topography. Where a range of mountains occurs in the Crown land, then it must be included if it is twenty miles away, for it has been definitely established that fires are started on plains 3,000 feet below by bark and debris blown from trees burning on a range twenty miles away. The wind reaches hurricane force, and even on the plains it reached 40–50 m.p.h. at the height of the fire on January 14. Where the forest reserve is surrounded by plain country, the protective belt may be safely made narrow. Everywhere throughout the protection belt roads must be made and look-out tow erected. Instant detection is the first step, a then immediate suppression. Wireless is a valua aid to both these services, making communicati possible between the towers, the fire suppressi gang and with headquarters. All this is going cost a great deal of money, the failure to provi which in the past is the main reason for t disaster. Conflagrations are not inevitable; t forest departments of Australia have sho this in the case of fires starting with their forests, and all that is necessary is extend the foresters' jurisdiction and operatio to cover the land held under grazing occupan outside.

The tragic loss of life has brought the questi of safety measures very much into the foregroun Dug-outs proved very valuable to forest mill-han and others during the last outbreak and ma lives were saved through them.

REACTIONS WITH MONOLAYERS AND THEIR BIOLOGICAL ANALOGIES

By PROF. ERIC K. RIDEAL, M.B.E., F.R.S., AND DR. J. H. SCHULMAN,
DEPARTMENT OF COLLOID SCIENCE, CAMBRIDGE

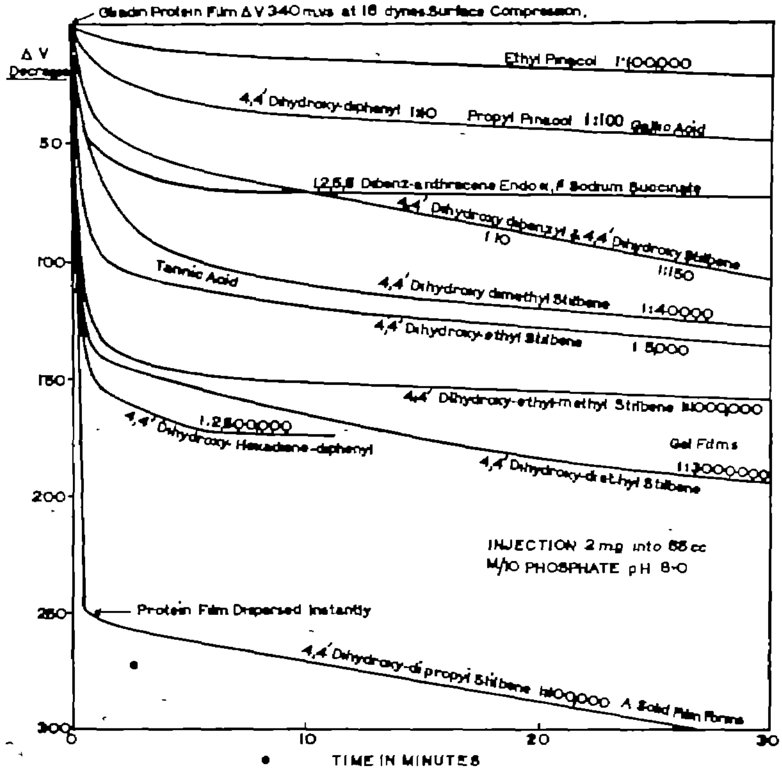
THE film technique permits us not only to examine the progress of chemical and enzyme reactions in monolayers but also to investigate mixed films, for example, lipo proteins, and the effects of injecting various reactants beneath monolayers. It has been found[1] that the reactions of monolayers of lipoids such as cholesterol with substances injected into the substrate are dependent both on the nature of the polar group and on that of the hydrocarbon 'tail' of the injected reactant. Similar conclusions can be drawn as to the extent of reaction with monolayers of proteins. The possibilities in this case are somewhat more complex, for the protein monolayer must be regarded as a triplex system, the extended polypeptide chains separating an upper hydrophobic layer from a lower hydrophilic one, the latter containing the polar groups of the side chains of the protein.

It is possible to separate the various factors which govern the adsorption by, or the penetration into, a monolayer of such a structure. These naturally include not only the usual criteria of water and oil solubility but also more specific terms, such as the interaction of polar groups and special steric configurations which permit of adlineation of specific hydrophobic portions of the molecules. We include also not only the effec produced by changing the number and spacing o polar groups in the reacting molecule, that i multiple point contact, but also the structure o the hydrophobic portions which may or may no be conducive to close packing of the reactant i a sheet below the protein monolayer.

We have examined *inter alia* a number o œstrogenic compounds[2] of which the $p.p'$-dihy droxy diphenyl hexadiene and stilbene derivative form a definite series in which the ratio of hydrophobic to hydrophilic portion could be varied These show marked differences in œstrogeni activity with a sharp maximum at $p.p'$-dihydrox diphenyl hexadiene and $p.p'$-dihydroxy diethy stilbene or dibenzyl. The œstrogenic activity fall some thirty to fifty-fold on increasing or decreasin the number of CH_2 groups in the molecule by two

In the accompanying figure are shown th extents of interaction as measured by the chang in surface potential with a gliadin monolayer o a substrate buffered at pH 8 on injection o 3 mgm./100 c.c. of reactant into the substrate The œstrogenic activities of the various compound are likewise included. It will be noted that reaction sets in rapidly, but equilibrium is only finally attained after some 15–20 minutes, and t there is a parallelism between the œstrogenic ivity and the protein adsorption except in the first d the last members—points we shall refer to later.

We observe that in apparent conformity with ube's view there is a marked increase in sorption with increase in the number of CH_2 oups in the molecule, and that this adsorption cut down by the insertion of polar groups. This fect is clearly exemplified in comparing the thyl stilbene or dibenzyl compounds with the rresponding pinacols. If, however, reactive lar groups, for example, the phenolic hydroxyl, d been inserted instead of the primary alcoholic groups in the methyl or ethyl pinacols, a marked increase rather than a decrease in adsorption would have been observed, for the following compounds react in order of increasing adsorption on both amine and protein monolayers: cresol, *gallic acid, digallic acid, purpurogallin and tannic acid.* This order is, however, reversed to give a normal Traube series when these substances are injected under a relatively non-reactive monolayer such as a long-chain acid. A wide variety of substances have been examined from this point of view, namely, their extent of interaction with protein monolayers, and it has been found that there is a direct parallelism between their extent of interaction and their lethal action on Paramecia.



We note a further biological analogy in that long-chain hydrocarbon derivatives with one reactive polar group at the chain end penetrate monolayers and biologically possess lytic activity: if a second spaced polar group be inserted the lytic and penetrating properties are lost, the substance becomes an absorbant, is packed into the double layer beneath the film, and biologically acts as an agglutinating agent.

Another significant biological similarity has been noted when we measure the extent of penetration of a series of substances *containing identical* hydrophobic 'tails', for example, a C_{16} chain, but with different head groups into a monolayer of a typical lipoid such as cholesterol. In all cases the extent of interaction, as measured by the increase in surface pressure caused by the injection of 0·33 mgm./100 c.c. under a film of cholesterol, originally extended to 40 A.^{2} per molecule, is found to be closely parallel to the hæmolytic activities and lethal activities on Paramecia of these substances.

These latter can be placed in order both of monolayer penetration and of biological activity as follows:

$$R\overset{+}{N}H_3 > RSO_4' > RSO_3' > RCOO' > R\overset{+}{N}(CH_3)_3 >$$
$$R\overset{+}{N}H(CH_3)_2 > \text{Bile acids.}$$

We may conclude that the most reactive group in the protein macromolecule is the amino group since the -NH-CO- group is poorly reactive, a point of some interest when we examine the reactions of lecithin and of cephalin. This order of head group reactivity receives confirmation when penetration into monolayers containing these head groups is examined, that is, on inverting the system. When we compare the reactivities of a series of long-chain compounds with identical head groups, it is found that biological activity and film penetration commences at about C_8 when attached to a very reactive head group and reaches a maximum value at about C_{16}. It is interesting to note that it is not necessary for all the carbon atoms to be in the form of a chain; they may be enclosed in ring systems; thus activity commences with diphenyl derivatives. Optima are found in the bile acids, stearic acid, diethyl-stilbœstrol and benzpyrene oxidation products.

We have referred to the modification which must be introduced into either the Overton Meyer or Traube concepts of biological activity, namely, lipoid solubility or capillary activity necessitated by the concept of specific head group interaction. We see that a definite limit is also set to the hydrophobic portion of the molecule, for we must take into account both the decreasing solubility in the aqueous phase causing difficulty in transport and also the ease of adlineation or packing having an optimum of C_{16}. We find that a new phenomenon, as exemplified in the figure, sets in with long chains, namely, dispersion of the monolayer, most marked in the case of 4,4′-dihydroxy dipropyl stilbene. It is possible that this phenomenon of film collapse and dispersion may be a generally important factor in setting the upper limit to the chain length or, more generally, the capillary activity of homologous series of biologically important substances, such as anæsthetics. This dispersion of protein films may have biological counterparts in adsorption on specific portions of the cell surface similar to the hæmolytic activity of long-chain compounds such as oleic acid, which readily disperses protein films. Another interesting parallelism has been observed in the surface reactivities and œstrogenic powers of two isomeric compounds (*p.p′*-dihydroxy diphenyl hexane), one being markedly differentiated from the other in both protein adsorption and in œstrogenic activity. Here models indicate that the *trans* arranged rings can pack laterally with one another in sheet form much more readily and with a greater degree of adlineation than the *cis* structure, imparting stability to the adsorption complex formed with the former substance.

In advancing these somewhat novel principles, based upon the hypothesis of a parallelism of film reactions and biological activity, it is desirable to point out exceptions. It is found, for example, that the pinacol 4,4′-dihydroxy propiophenone is a much more effective œstrogenic agent than eith its paramecidal activity or adsorption on prote monolayers would suggest. The view might advanced that on certain living tissues it can partly converted by enzymatic reaction to eith the extremely active 4,4′-dihydroxy diphenyl hex diene or to dihydrostilbœstrol. Another interestin exception is to be found in desoxycholic aci which is the only hæmolytic agent in the bile ac (c. 1 : 550) series and is likewise poorly lethal Paramecia. It is unreactive to films of protei cholesterol and glycerides, and in fact a specif interaction with fatty acids is involved, an observ tion which may be of importance in considerin the emulsifying and transporting properties of th bile acids in the intestine.

This method of attack permits us to investigat the nature of the coatings of cells of unicellula animals and plants by examining the effects lipoid or protein film penetrating or adsorbin substances on them.

Thus both red cells and Paramecium ar affected by lipoid and protein monolayer pene trating (cytolysing) or adsorbing (agglutinating agents, and we deduce that their surface structure must contain lipoproteins or consist of a lipoi protein mosaic; whereas certain other unicellula animals frequently found associated with Para mecia and, in addition, cilia of *Mytilus* are no affected by protein adsorbants or dispersants bu are readily influenced by lipoid penetrating agents and their coatings in consequence must be chiefl lipoidal in nature.

Examination of the carcinogenic hydrocarbon by the monolayer technique reveals the interestin fact that, whilst they themselves are unreactive they are readily converted into extremely reactiv water-soluble unstable photo-oxidation products These substances are not only reactive to protei monolayers like the water-soluble dibenzanthra cene endosuccinate (see graph) but are also para mecidal, a general parallelism between the bio logical activity and monolayer reaction bein maintained.

Finally, it may be suggested that the concept of specificity which we draw from the principl that both polar and non-polar interaction par ticipate in molecular adlineation in monolayers, applicable to biological reactions in general present us with a set of principles which permi of direct experimental application and theoretica attack.

OBITUARIES

Dr. Edward Kidson, O.B.E.

DR. EDWARD KIDSON, director of the Meteorological Office, Wellington, New Zealand, died ddenly on June 12 at the early age of fifty-seven ars.

Dr. Kidson belonged to a well-known Nelson and ristchurch family, but was born at Bilston, affordshire, on March 12, 1882. He received his hool and university education in New Zealand, aduating at the University of New Zealand with st-class honours in physics in 1904. His first post as that of assistant observer at the Magnetic bservatory, Christchurch, which led to his joining e staff of the Department of Terrestrial Magnetism the Carnegie Institution of Washington in 1908. efore the Great War he was engaged on magnetic rveys in South America, Newfoundland and ustralia, and he spent six months as magnetic bserver on the magnetic survey ship *Carnegie* longing to the Carnegie Institution.

During 1915–1919 he was on active service in the eteorological Section of the Royal Engineers with e Salonika Force. He was mentioned in dispatches d made O.B.E. for his war service. After the War returned to the Carnegie Institution and was ven charge of its Magnetic Observatory at atheroo, Western Australia. Kidson remained at atheroo from 1919 until 1921, when he joined the eteorological Service of the Australian Commonealth as assistant director.

In 1921 Kidson returned to New Zealand on being ppointed director of the Meteorological Office, ellington. The Meteorological Service of New ealand when Kidson took charge was in a very nsatisfactory state and the total staff numbered ly five. With characteristic energy he set to work build up a service based on modern scientific lines. idson's travels had kept him in touch with meteorogical progress in America and Europe; he was a an of science and appreciated the work of the orwegian school of meteorologists. He visited ergen in 1931 and 1935 and, aided by one of Dr. jerknes's assistants, who stayed a few months in ew Zealand on his return from the Antarctic, he troduced the Norwegian ideas into the work of his rvice and in this way broke new ground in the udy of meteorology in the southern hemisphere. e was fortunate in his choice of scientific assistants, nd with their aid built up a meteorological service, onsisting of forty-five members, which compares vourably from a scientific point of view with the eteorological service of any other country.

Kidson's own scientific work, with the exception f the reports he prepared on terrestrial magnetism hile on the staff of the Carnegie Institution, was evoted almost entirely to meteorology. He wrote xtensively on the climate of New Zealand, and as interested in the investigation of the upper atmosphere. He published papers on weather forecasting and the theory of tornadoes. He was particularly interested in Antarctic meteorology; his chief published work was a thorough discussion of the meteorological records of Shackleton's first expedition (1907–9) and at the time of his death he was on the point of completing a compilation and discussion of the meteorological data obtained on Mawson's later expeditions.

Kidson's sound scientific knowledge, coupled with a wide and sane outlook on international meteorological problems, was unsurpassed in the southern hemisphere, and his early death just at the time when such qualities are especially required is a real tragedy.

G. C. SIMPSON.

Dr. C. H. Mayo

DR. C. H. MAYO, who died on May 28, was one of the greatest of contemporary American surgeons. During his active career of nearly fifty years, he was associated with his elder brother, Dr. W. J. Mayo, in founding and fostering the Clinic in Rochester, Minnesota, which bears their name. In their lifetime, this has expanded rapidly until now it is a huge centre of medical and scientific effort, an expansion the more remarkable because of the small size of the town and its distance from main roads and railways.

Dr. Mayo's scientific work cannot be considered apart from the development of the Clinic. At an early date the brothers determined to devote the profits of the enterprise to the furtherance of medical education and research, and gradually brought together a team of workers which included clinicians, experts in preclinical subjects and, notably, experts in the related sciences of biochemistry and biophysics. Thus their object has come to be the intensive study of all aspects of disease, as well as its treatment. This type of organization was an admirable background for Dr. Mayo's substantial contributions to the surgery of the thyroid gland. He was one of the earliest to operate for thyrotoxicosis, and did much to eliminate the technical difficulties associated with this procedure. Later he was able to utilize the discovery by his colleagues, H. S. Plummer and Boothby, that the administration of iodine reduced the dangers of operation, and to add and adopt further refinements in pre-operative and post-operative care, and in surgical technique. His work on transplantation of the ureters to the colon in cases of ectopia vesicæ was also outstanding, and in his hands this was a safe and satisfactory operation. He approached the problem as a biologist, and in inducing the rectum to function as a cloaca he displayed great technical ingenuity and a sturdy respect for the conservation of renal function.

Dr. Mayo was essentially a general surgeon, and his nimble mind attacked and solved many diverse problems of technique. In the operating theatre he combined wise conservatism with amazing resourcefulness, and one of his delights was to introduce and perfect operative details, many of which are in general use. His reputation was international, and this, with his personal charm, made him a welcome figure at surgical meetings the world over. Based as they were on great experience and uncommon clinical acumen, his opinions were listened to with respect, and both abroad and in the Clinic he did much to secure the free interchange of surgical ideas and ideals.

Prof. Edgar Zunz

WE regret to announce the death on June 11 after a short illness of Dr. Edgar Zunz, professor of pharmacodynamics and therapeutics in the University of Brussels and an eminent personality in the Belgian medical world. He was born at Charleroi on November 9, 1874, and received his medical education at Brussels where he qualified with distinction in July 1897. Having won a travelling scholarship, he spent some time at Heidelberg in studying organic chemistry in Gattermann's laboratory, and later at Strassburg in Hofmeister's laboratory of biochemistry and at Bern under Kronecker, the physiologist. On his return to Brussels in 1900 he was appointed assistant to Prof. Victor Jacques in the laboratory of pharmacodynamics and therapeutics. In the following year he presented a thesis to the University of Brussels on the digestion of albuminoid substances, which gained him the degree of doctor in physiological science. In 1906 he was appointed an *agrégé* in the Brussels medical faculty, and gave a course of practical demonstrations in medical chemistry. In 1909 he became lecturer to postgraduates in toxicology and in 1913 instructed students in the elements of pharmacography. During the War he did valuable work as director of the medical department including the care of the gassed at the Ocean Ambulance at La Panne. In 1919 he was appointed professor of pharmacodynamics and therapeutics in the Brussels faculty of medicine and held this post until his death.

Zunz was a remarkably fertile writer. His two chief works were his treatises on general and special pharmacodynamics published in 1930 and 1932 respectively. He also collaborated with Prof. Terroine in a work on basal metabolism (1925), and contributed articles on coagulation of the blood to Roger and Binet's text-book of physiology and on the regulation of the composition of the blood to the fourth volume of the "Encyclopédie Française". He further contributed many papers to Belgian and foreign journals on the digestion of proteins, the properties of proteoses and peptones, coagulation of the blood, secretion of adrenalin and insulin, action of the alkaloids of opium, the process of digestion, phenomena of adsorption and surface tension, and the effects of poison gases. He took an active part in the campaign against alcoholism and was president of the International Congress Against Alcoholism held at Antwerp in 1928 as well as president of the scientific committee of the World Union Agai Alcoholism.

Zunz was the recipient of many honours. In 1 he was elected a member of the Belgian Ro Academy of Medicine, of which he became presid in 1934, and in the following year was president of annual congress known as the Journées Médicales Bruxelles. He was also an Officer of the Order Leopold, Commander of the Order of the Crov Officer of the Legion of Honour, honorary doc of the University of Montpellier and correspondi member of the Royal Academy of Medicine of Ron

J. D. R

Prof. Rudolf Fick

PROF. FICK, who died on May 23 at the age seventy-three years, retired from the chair of anato in the University of Berlin in 1935. He brought do to the rising generation of German anatomists t great traditions of Gegenbaur and of Koellik Indeed Prof. Fick's first appointment was in Koellike department at Würzburg. His earliest research wo was on the ripening of the cells of reproduction, whi led to his becoming assistant to Wilhelm His Leipzig. There the nature of his inquiries took a n direction; he applied to the study of the human bo a more complete understanding of mechanics th had been done previously. The results of his studi are embodied in his "Handbuch der Anatomie u Mechanik der Gelenke" (1904–1911; 3 vols.). H fellow anatomists admired his researches more th they studied them. In all he did there are to be se care and accuracy. This is particularly true of h pioneer research into the anatomy of the orang- carried out on adult animals which died in t Zoological Gardens of Leipzig towards the end of t nineteenth century.

Prof. Fick was born in Zurich, the son of t distinguished physiologist. Although born in Swi zerland he was intensely German in feeling and aspiration. From an assistantship in Leipzig he w appointed to the German University in Prague 1905. Four years later he was invited to Innsbruc In 1917 he was called to Berlin to fill the highe post in anatomy in Germany—a prize award perhaps more because of his outstanding meri as a man than of the importance of his research in anatomy. His chief aim in life was to teach h students; he preferred to spend his energies and tim in the preparation of anatomical specimens to illu trate his lectures rather than on researches for t advancement of anatomy.

WE regret to announce the following deaths:

Mr. Henry Havelock Ellis, a pioneer in the psych logy of sex, on July 8, aged eighty years.

Prof. R. I. Meyer, editor of the latest edition "Gmelin's Handbuch der Anorganischen Chemie" known for his work on the rare earths, on June 1 aged seventy-four years.

Prof. G. E. Nichols, professor of botany an director of the Botanical Gardens at Yale University on June 20, aged fifty-seven years.

NEWS AND VIEWS

rof. F. C. Minett

FRANCIS COLIN MINETT, who has just been ap- ointed director of the Imperial Veterinary Research stitute of the Government of India, was educated King Edward's School, Bath, from 1899 until 907, and in the latter year entered the Royal eterinary College. Two years after obtaining the iploma of membership of the College, he was warded a Ministry of Agriculture research scholar- hip and studied at the Pasteur Institute in Paris nd at the Veterinary School in Alfort. On the out- reak of the Great War, he joined the R.A.V.C. and roceeded to France with the Expeditionary Force. n the following year he returned to Aldershot, here he was engaged in research and in the pre- aration of mallein for the diagnosis of glanders—at hat time a problem of urgent military importance. rom 1921 until 1924 he served in Egypt, and in the atter year resigned his commission upon receiving n appointment under the Foot-and-Mouth Disease ommittee. He was awarded the D.Sc. in veterinary cience of the University of London in 1927, and in he same year, upon the retirement of Sir John McFadyean, was appointed director of the Research nstitute in Animal Pathology at the Royal Veterinary College, and, in 1933, when the posts became amal- gamated, he was appointed professor of pathology nd director of the Research Institute.

DURING the past twelve years, Prof. Minett has contributed generously to the study of many problems associated more particularly with diseases of economic mportance among farm animals. In this connexion, special reference should be made to his work upon bovine mastitis, Johne's disease and contagious abortion of cattle, as a result of which, measures for the more effective control of these diseases have been established. Important as his researches have been, it is safe to say that one of his chief claims to recognition lies in his ability as a teacher. Indirectly, as well as by direct contact with his students and junior members of his research staff, he has advanced the study of veterinary pathology to a marked degree.

Bicentenary of Du Fay (1698–1739)

ON July 16, 1739, the death occurred of the French man of science, Charles-François de Cisternay du Fay, who though he wrote memoirs on many subjects and was superintendent of the Jardin des Plantes, is remembered to-day for his electrical experiments and observations. Born in Paris on September 14, 1698, he was an officer in the French Guards, and for a time followed a military career. Ill-health, however, led to his resignation and he then turned to literary and scientific pursuits. He was admitted to the Academy of Sciences in 1733 and contributed papers on geometry, astronomy, mechanics, chemistry and botany. He was especially interested in the electrical experiments of Stephen Gray, and suspending himself by silk cords, as described by Gray, he observed that when he was electrified, and another person came near, there issued from his body pricking shoots, making a crackling noise. The Abbé Nollet (1700–70) was associated with these experiments, which he afterwards extended. Du Fay also discovered two kinds of electricity which he named the *vitreous* and *resinous*, and he made attempts to formulate a theory of electric phenomena. A man of great industry, as superintendent of the Jardin des Plantes he did much to rescue that institution from neglect, and it was through him that Buffon became his successor.

Julius Cohnheim (1839–1884)

PROF. JULIUS COHNHEIM, the eminent experimental pathologist, was born on July 20, 1839, at Demmin in Pomerania. He studied medicine at the universities of Würzburg, Marburg, Greifswald and Berlin, where he qualified in 1861 with a thesis on suppuration in serous membranes. After acting as an assistant to Virchow in Berlin and serving as an army surgeon in the war with Austria, he was appointed professor of morbid anatomy at Kiel, where he remained until 1872. He was then transferred in a similar capacity to Breslau and finally occupied the corresponding chair at Leipzig in 1878, where he stayed until his death six years later. Cohnheim was a highly skilled technician, and made several valuable contributions to microscopical science, among which may be mentioned his methods for demonstrating the nerve endings in the cornea, the structure of striated muscle and the phenomena of inflammation. His successful inoculation in 1868 of tuberculosis in the anterior chamber of a rabbit's eye, thus proving the disease to be infectious, is an important landmark in the history of tuberculosis. His principal literary work is represented by his lectures on general pathology published in 1877–80 and translated in 1888–90 in the New Sydenham Society's publications, in which he dealt with the pathology of the circulation, nutrition, digestion, respiration, genito-urinary organs and animal heat. He also published several valuable articles on malignant growths, trichinosis and the bone marrow in anaemia. His stimulating lectures attracted a large number of students from all parts of Germany, and he had many men who later became eminent among his audience, including Heidenhain, Litten, Welch and Neisser at Breslau and Roy and Councilman at Leipzig. He died at the early age of forty-five years on August 15, 1884, from the effects of gout.

New Long-Distance Air Liner

PRELIMINARY details of a new civil transport aeroplane, the Fairey C.I., have just been made public. It is a low-wing monoplane fitted with four Bristol 'Perseus' sleeve-valve engines of 1000 h.p. each. The body is of a circular section monocoque construction, arranged to carry thirty passengers.

The undercarriage is of tricycle form so placed that the machine can land and stand with the cabin horizontal, which will increase the comfort of the passengers and facilitate loading up when on the ground. The wheels are retractable during flight. The cabin is air-tight, and conditioned air at ground-level density is maintained when flying at altitudes. The machine is fitted with an automatic pilot, relieving the pilot of most of his physical work, and making him more analogous to the captain of a ship. The whole of the mechanical detail is controlled from the flight engineer's cabin, who has actually sixty-four dials on his instrument board, dealing with matters varying from engine and flying performance down to the condition of the air in the cabin. A new feature of this machine is an auxiliary wing that can be retracted when not required. It is shaped like the more familiar trailing edge flap, and thus can be used as an air brake for reducing landing speeds as well as providing the extra surface for increasing the flying speed range. This additional surface allows for a wing loading of 25 lb. per square foot for taking off and landing, which is increased to 32 lb. per square foot while flying with it retracted. The estimated speeds of the machine are 275 m.p.h. maximum, and 220 m.p.h. cruising, and its air endurance with the full load of passengers will enable it to operate non-stop to any European capital. With a decreased pay load it will be capable of fast non-stop services on the Empire routes.

Neanderthal Man in Italy

IN more respects than one, the discovery of a skull of Neanderthal man in the Guttari cave at Monte Felice Circeo, about sixty miles south of Rome, is of unique significance for the study of the chronology and distribution of Mousterian man in Europe of the palæolithic period. Owing to conditions affecting the use of the cave by man, it is possible to fix the date of occupation within tolerably accurate limits, while the sealing of the cave in Mousterian times which brought that occupation to a close, has not only preserved the evidence of Neanderthal man and his domestic economy intact but also saved it from the superposition of the debris of subsequent intrusions—conditions unique in caves of Mousterian occupation. The skull, now the third of the type known from Italy, was found on February 25, 1939, by Dr. A. C. Blanc of the University of Pisa, who with the Abbé Breuil, discovered the second of the Italian Neanderthal skulls. Dr. Blanc had already examined thirty-one caves at Monte Circeo and found in them evidence of both the Mousterian and Aurignacian cultures, but the present find was made in a cave which had been discovered on the previous day only by its owner, S. A. Guttari.

THE skull lay on the floor of an inner chamber of the cave among stones which appear to have been laid in a circle around it, while underneath it were bones of Equus, Bos, Cervus and Sus, some of which had been intentionally flaked. The floor of the whole cave was covered with fossilized mammalian bones, antlers and skulls, including, in addition to tho mentioned, hyæna and others, while elephant bon were found in a pool. All belonged to a war climatic phase. This Neanderthal skull is the mo perfect yet known, and in size approaches that La Chapelle aux Saints. A fracture of the rig temporal region points to a violent death; and t base of the skull has been opened extensively an the greater portion of the occipital foramen d stroyed. The date of occupation is fixed by relatio to the oscillation of sea-level at somewhere betwee 130,000 and 70,000 years ago; and Sir Arthur Keit who contributed a prefatory note to an accoun with illustrations, of Dr. Blanc's discovery in th *Illustrated London News* of July 5, regards the relics of Neanderthal man as contemporary with th lowest level of the Grotte des Enfants, Mentone.

Recent Additions to the British Museum (Bloomsbury

SOME striking examples of West African art wer among the more important of the recent addition to the ethnographical collections of the Britis Museum, which were reported at the meeting of th Trustees on July 8. Of these one was a gift of th National Art Collections Fund—a cast bronze hea which was excavated at Ife, the religious centre o the Yoruba people, and is said to represent Olokun the Yoruba deity of the sea. Discovered in 1938, i is in good condition, and shows traces of red pain on the head-dress. Probably it belongs to th fifteenth or sixteenth century, though the date i uncertain. Its modelling is of a quality uniqu among the artistic productions of negro Africa, and bears comparison with the finer sculptures of civilized art. The second example of African art is a carved ivory tusk from Benin, which bears figures of fish and animals, symbolizing the king in his supernatural aspects. There is a receptacle for magical 'medicine at the larger end. No similar example is known. The gift to the Department of Manuscripts of the diaries of Robert Needham Cust, an Indian civil servant well known as an orientalist among scholars of the nineteenth century, will be welcomed by all who are interested in the history of Indian and oriental studies. The diaries were presented by his son, Mr. R. H. H. Cust.

Utilization of Coal

THE British Coal Utilization Research Association held its first annual meeting in London on June 28, when Sir Evan Williams, the president, gave an account of its first year's work, which has been largely concerned with the erection and organization of its research station in Fulham. It has been a subject of reproach that the coal industry has been largely indifferent to promoting efficiency in the utilization of coal. They now foresee, the president said, that the future will call for fuels of accurately controlled characteristics; the development of these is being investigated. The programme of research includes work on pulverized fuel firing which, it is believed, will play an increasingly important part in industry, and also on combustion in the fuel bed.

he study of producer gas is to receive greater tention in view of its present importance in heavy dustry and its potential application to mechanical ansport. Great store is laid by the coal industry n the open coal fire, and efforts are being made to inimize its admitted defects—smoke and labour. is recognized that coal-burning appliances have ffered in comparison with gas and electrical ppliances owing to the neglect of scientific principles design, and it is hoped to raise the standards of erformance and eliminate inferior and ineffective ppliances. Efforts are being made to advance the se of coal for cooking. A solid fuel cooker has been esigned for use on railways. Some of these have een installed on trains, including the *Coronation cot*. It is believed that gravity feed firing will play considerable influence on hotel and institution ookery in the future.

Collective and Economic Security

POLITICAL and Economical Planning (P E P) has ssued two broadsheets dealing with the economics of ollective security and instruments of economic ecurity. In the former, relations between economic olicy and a fresh effort to realize collective security re discussed and the necessity of military support or economic collaboration is emphasized, and the mportance of ascertaining how far geography and he balance of strategic forces would permit military ssistance if needed before inviting smaller countries nto a system of collective economic security. The maintenance of peace through collective political and conomic security involves the application of principles similar to those which would be appropriate in ime of war. The measures of self-defence now equired of a system of collective security may be lassified as those required for preserving and promoting the free exchange of goods and services between members of the system; steps needed to nsure that the advantages of participation in economic relations on those terms should no longer be available to nations which do not subscribe to the conceptions inherent in the free exchange system and which now only participate in that system to destroy; and measures for extending assistance to neutral countries to enable them with safety to enter the orbit of the free system. Civilization's resources, it is urged, should be used to maintain civilization, and the main economic implications of a policy of collective security are discussed in some detail, including the question of reciprocal aid, the utilization of limited resources, the difficulty of overvalued currencies, the possibility of organizing markets and Nazi political and economic exploitation. If civilization is to be preserved it cannot be in isolation. Its basis is international, and there is no alternative to collective measures.

THE second broadsheet, emphasizing the need for industrial reorganization, classifies the possible measures under four heads, according to their connexion with Government commercial policy, with the improvement of trading methods, with the finance of international trade and with export and import subsidies. The absence of any coherent British trade policy is criticized. The United Kingdom has a strong bargaining weapon for securing increased reciprocity in commercial relations with individual States in view of the importance to them of British import purchases, and it is suggested that 'most favoured nation' treatment might be withheld from countries which resort to unfair trade practices. Much could still be done to improve the mechanism of economic co-operation and the importance of control schemes and cartels being operated in the public interest and particularly in the interests of economics is stressed. The questions of export credits, import subsidy, and of selecting the appropriate measure for different purposes are then discussed, the final emphasis being laid on the need for more moral courage to form the nucleus of a system of collective economic security in which the benefits of free exchange would be limited to the free exchange group.

Employment in 1938

THE report of the Ministry of Labour for the year 1938 shows that on the average for the year the numbers in employment were about 120,000 less than in 1937 although higher than in any previous year except 1937, and more than 20 per cent higher than in 1924, when the series of comparable statistics was begun (Cmd. 6016. London: H.M. Stationery Office, 1939. 2*s*. net). The seasonal fluctuations were less than usual, the maximum variation in the rate of unemployment among insured persons in the general scheme being only 0·5 per cent as against variations of from 2 to 5 per cent in previous years. Seasonal improvement in the first half of the year, however, was much less marked than usual in the building and contracting industries, brick manufacture and the distributive trades, and was almost entirely offset by a decline in metal and metal goods manufacture, engineering, the textile industries, especially in the cotton industry, and the normal slackening in coal mining. In the second half of the year the seasonal decline in building and public works contracting, transport, distribution and the hotel and boarding-house service was counterbalanced by improvements in the textile industries, metal goods manufacture, and the vehicle and mining industries. The effects of the recession of 1937–38 were spread very unevenly over different areas of the country, being most marked in the north-western area, in which employment declined by 7·5 per cent, mainly through contraction in the cotton industry. Wales suffered severely with a fall of 5·4 per cent, mainly in the iron and steel and tin-plate industries. In the Midlands there was a fall of 3·4 per cent and in the south-eastern division no change.

REFERENCE is made in the report to the policy of the Ministry in regard to the admission of foreign workers. Of the 22,347 permits granted during the year, 61·7 per cent were for employment in private domestic service. The figures do not include persons admitted to the United Kingdom by the Home Office as refugees and who have been allowed to enter into employment as domestic servants in private households. The Government policy of locating new factories and other establishments required in connexion with the defence programme in areas of heavy unemployment, so far as strategic and other practical considerations allow, has led during the year to the setting up of new establishments employing many thousands of workers in the Special Areas and in other areas of heavy unemployment. With regard to juvenile employment, the report points out that the estimated number of juveniles aged 14–17 available for employment was about 159,000 less than at the end of 1937. The numbers aged 14 entering the industrial field have been decreasing since 1934, and by 1934 the decline in the birth-rate after 1920 had influenced the numbers in the whole 14–17 group. Although prospects of employment for juveniles remained fairly good in most parts of Great Britain, they were less bright than in 1937.

British Trust for Ornithology

THE fifth annual report of the British Trust for Ornithology reveals the remarkable progress made in the co-ordination of field studies in Britain in recent years, and much space is given to the results of these field investigations. They include the lapwing habitat inquiry, and that of the distribution of the corncrake, which is to be continued this year. In 1938, 1200 completed returns were received referring to the corncrake and noting its decreasing numbers, most marked in Ireland and least in Scotland; efforts are being made to get information from the Continent, where the species is also decreasing. The survey of black-headed gull colonies had 150 observers, and shows that few coastal counties have been colonized in the past twenty-five years, but there has been a marked inland spread. The sample census of heronries shows an increase of breeding stock in many places, and three heronries in England now have between 120 and 150 nests. The bridled guillemot inquiry shows that few of this variety are in the English and Welsh colonies, but the percentage increases from about lat. 56° N. The woodcock inquiry showed by ringing that occasional British woodcock accompany the winter migrants when they return to their native breeding haunts. The woodland bird inquiry gave special attention to the British sub-species of birds, which can be divided into four groups showing thirty-seven distinctive races of bird entirely confined to Britain. A new inquiry on the redshank is planned for 1939–40 and a hatching and fledging inquiry will extend nationally the work started at Whipsnade Bird Sanctuary.

Tuberculin Tests in Cattle

BOVINE tuberculosis is one of the most serious scourges that afflicts cattle in Great Britain, causing an annual loss which has been estimated to amount to £2,000,000 annually. The disease in dairy herds is also responsible for much human tuberculosis, particularly in children. The eradication of tuberculosis from herds is now receiving serious attentio The detection of tuberculous animals by means the tuberculin test is employed in all schemes f the eradication of bovine tuberculosis, but in rece years modifications in methods of preparation tuberculin and in its application have been intr duced. The need for detailed research into vario problems associated with the tuberculin test w recognized by the Joint Tuberculosis Committee the Medical Research and Agricultural Resear Councils, and work on the subject was undertak at the Institute of Animal Pathology, Cambridge, b Prof. J. B. Buxton and Mr. R. E. Glover, and t results of their investigations are published in report issued by the Agricultural Research Counc ("Tuberculin Tests in Cattle". H.M. Stationer Office. 1s. 6d. net). After dealing with the differen methods of applying the tuberculin test, sections a devoted to the value of several types of tuberculi sensitization and desensitization of tuberculous an non-tuberculous cattle to tuberculin, and the po sibility of 'doping' against the various tests. Exper ments are also described in which attempts wer made to sensitize normal cattle to tuberculin itsel and finally, the significance of reactions, resultin from infections with organisms closely allied to th bovine tubercle bacillus, is discussed.

University of London: Principal's Report

IN recent years a corporate university spirit ha made itself increasingly felt in London. Its growt has, naturally, been stimulated by the erection o the imposing block of central buildings in Bloomsbur and the grouping there in association with them o several important schools and institutes. It wi receive a further notable impulse from the openin of the new Students' Union. The Union has alread proved its value as a centre of student life, and Lor Nuffield's gift last year of £50,000, added to a gran of £25,000 from the National Fitness Council an one of £35,000 from the University Grants Committee has enabled the Court to proceed to the constructio and equipment on a generous scale of a permanen home for it. Among other interesting items of th Principal's report may be mentioned: a close association with external students through a ne system of communicating detailed examination result to all Intermediate Examination candidates and t the institutions responsible for their training; a ne Certificate in Natural History for prospective teacher of nature study in primary schools; and the establishment of an editorial board under the chairmanship of Sir Bernard Pares, who is retiring from the directorship of the School of Slavonic and East European Studies, to be responsible for the publication of the *Slavonic and East European Review*.

New Entomological Journals

THE Entomological Society of Southern Africa was founded in 1937 and the first volume of it *Journal*, dated March 30, 1939, has come to hand. It contains seven papers, covering a very wide range of subjects, including taxonomic studies on Diptera

(B. de Meillon, H. K. Munro), the biology of a nest-living Sarcophagid (A. Cuthbertson), studies of new Thysanoptera (C. Jacot-Guillarmod), descriptions of South African moths (A. J. T. Janse), the control of temperature and humidity in small cabinets (M. N. S. Immelman) and finally on the general classification of insects (J. Omer-Cooper). The journal is excellently printed and illustrated, and the first volume, including also index, obituary notices and list of members of the Society, extends to 163 pages. It is obtainable from the Honorary Secretary of the Society, P.O. Box 103, Pretoria, South Africa, and from N. V. Swets and Zeitlinger, Keizersgracht 471, Amsterdam, Holland. The price of the volume is £1 2*s.* 6*d.*

It is announced in the *Bee World* that an All-India Bee-Keepers' Association has been founded with an official organ, the *Indian Bee Journal*, the first issue of which appeared in January 1939. Owing to various causes, modern apiculture has an uphill journey in order to take its appropriate place in the scheme of Indian agriculture. The difficulties are being surmounted and the inauguration of the above Association and its *Journal* is likely to become an important factor in future progress. The address of the Association is Jeolikote, Naini Tal, U.P., India, and the annual subscription to the *Journal* is 3 rupees for one year, and proportionately less for two or more years.

Earthquakes during April 1939

According to the Central Seismological Bureau at Strasbourg there were 152 earthquakes each recorded at more than one observatory or experienced by people during the month of April. This was 52 more than during March (Nature, June 10, p. 988). The greatest number recorded on any one day was on April 6, when 14 occurred, and the least number recorded on any one day was 2 on each of April 8, 9, 28 and 30. The most important shocks during the month were probably those of April 1 (strength VIII) felt near Mostaganem in Algeria, April 18 at 6.23 G.C.T. in Chile (epicentre 27° S., 70° W. approx.), and that of April 30 felt at Guadalcanar and several other places in the Solomon Islands. The next most intense were the earthquakes of April 5 with epicentre near 20° S., 168° W., in the New Hebrides, April 21 at 4.29 G.C.T. (epicentre near Yeso), and April 23 at 16.23 G.C.T. (epicentre in the Atlantic near 1° S., 17° W.). Apart from these individual shocks there appears to have been a good deal of moderately intense seismological activity in Italy as earthquake shocks have been experienced at Livorno on more than one occasion, in the Frioul district and near Mont Amiata.

British Standards for A.R.P. Requirements

The Home Office Air Raid Precautions Department has arranged with the British Standards Institution to prepare and issued on its behalf a special A.R.P. series of British standards for air raid precautions purposes. The preparation of these standards will be under the control of a special advisory committee, and in accordance with the usual practice of the British Standards Institution will be carried out in the closest co-operation with Government departments and the industry concerned. All communications relating to this work should be addressed to the British Standards Institution, 28 Victoria Street, Westminster, S.W.1.

Research in Pathology at Leeds

The report for the years 1937 and 1938 of the Department of Pathology and Bacteriology of the University of Leeds, by Profs. Matthew Stewart and J. W. McLeod, has recently been issued. A summary of the routine examinations carried out is first given, followed by abstracts of the research work that has been done. This includes investigations on cases of silicosis and asbestosis, studies on the morbid anatomy and histology of chronic arthritis and its treatment with gold salts, and investigations on the morbid histology of diphtheria caused by the three types of the diphtheria bacillus. A report on cancer research is also contributed by Prof. R. D. Passey.

Conference on Engineering Education and Training

A Conference on Engineering Education and Training will be held at the Institution of Civil Engineers during February 6–8, 1940. Sir Clement Hindley, president-elect of the Institution, will preside over the Conference, which is being organized by a general committee representative of engineering institutions, universities, technical schools and colleges, engineering consultants, industrial organizations, Government departments and other interests. It is proposed to publish a number of papers, to be circulated in advance, which will form the basis of discussion at the technical sessions of the Conference. Inquiries should be addressed to the Secretary, Institution of Civil Engineers, Great George Street, London, S.W.1.

Two Large Sunspots

Two large groups of sunspots were conspicuous on the sun's disk during the past week. The larger of these groups, in latitude 4° south, appeared over the sun's east limb on July 3 and became a complex group with an area exceeding 1700 millionths of the sun's hemisphere. Its time of central meridian passage was July 9·3 U.T. The other group arose from a pair of tiny spots seen on July 4 in north latitude 6°. Shortly after its central meridian passage on July 8·2, it had reached an area of 1000 millionths.

British Empire Cancer Campaign

At the seventy-first quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on July 10, the following grants were approved: £400 to Mount Vernon Hospital for the employment of Prof. F. Weigert for research on a special biochemical problem; £495 to the Strangeways Research Laboratory, Cambridge, for the salary of its physicist, Dr. D. E. Lea, and £400 to Sir Robert Muir and Dr. P. R. Peacock for research to be carried out at the Glasgow Royal Cancer Hospital by Dr. Stephan Beck. This brings the total grants made to date by the Campaign for cancer research for the year 1939 to more than £49,000. The formation of a University of Cambridge Research Centre of the British Empire Cancer Campaign was approved. The initial Committee to supervise this Centre will consist of the Vice-Chancellor, Prof. H. R. Dean, Prof. J. A. Ryle, Sir Frederick Gowland Hopkins and Dr. Honor Fell, augmented later by other scientific workers at Cambridge. In future this Centre will co-ordinate all the cancer research being carried out at Cambridge and will itself initiate and direct research in the same way as the recently formed University of Oxford Research Centre of the Campaign. The Grand Council acceded to the request for affiliation from the Cancer Research Fund Committee (1934) of Northern Ireland, which now provides a link between the work of the Campaign and the cancer research being carried out at the University of Belfast and in Ulster generally. The following were elected members of Grand Council: Prof. J. A. Crowther (professor of physics in the University of Reading), Dr. H. T. Flint (director of physics at Westminster Hospital), Dr. R. W. Scarff (honorary secretary of the Scientific Committees of the Campaign) and Mr. D. G. Walker to represent the British Dental Association.

The Colonial Service: Recent Appointments

THE following appointments and promotions in the Colonial Service have recently been made: W. T. S. Brown, assistant conservator of forests, senior assistant conservator of forests, Gold Coast; F. S. Danks, assistant conservator of forests, Cyprus, assistant conservator of Forests, British Guiana; H. W. Moor, senior assistant conservator of forests, divisional conservator of forests, Gold Coast; G. M. Tolmie, assistant conservator of forests, senior assistant conservator of forests, Gold Coast; B. E. Frayling, chief inspector of mines, Tanganyika Territory, chief inspector of mines, Nigeria; J. K. Cox, inspector of plants and produce, agricultural superintendent, Gold Coast.

Announcements

DR. EMIL ABDERHALDEN, professor of physiology at Halle, and Dr. Max Planck, professor of theoretical physics at Berlin, have been elected honorary members of the Société Philomathique of Paris.

LORD HORDER has been elected president of the National Society for the Prevention of Venereal Diseases in succession to Sir Basil Peto, a founder-member and president since 1926.

AN exhibition is being arranged at the Science Museum, South Kensington, in conjunction with the Royal Photographic Society and the photographic industry to illustrate the history of photography from the time of its inception in 1839 down to the present day. The exhibition is being opened by the Marquess of Salisbury on July 20, and will be open to the public on July 22 for five weeks.

A SYMPOSIUM on "Growth and Development" to be held at North Truro, Massachusetts, during August 7–11 has been organized by the journal *Growth*. Grants towards the cost of the conference have been received from the Macy and Rockefeller Foundations. The topics for discussion, with their principal speakers, are: cell-division and differentiation (Prof. W. H. Lewis, Prof. P. W. Gregory); genes and development (Prof. Curt Stern, Dr. C. H. Waddington); chemical factors (to be announced) (Dr. J. Needham); regeneration, organization (O. E. Schotte, Prof. E. W. Sinnott); concept of organism (Dr. J. H. Woodger). Further information can be obtained from Dr. Philip White, Rockefeller Institute for Medical Research, Princeton, New Jersey.

THE People's League of Health has organized a scheme of clinical research to determine the influence of diet on expectant and nursing mothers in relation to maternal mortality and morbidity. Systematic observation and records are being collected at the ten London hospitals which are co-operating with the League in this research.

ACCORDING to the Central Dutch Office of Statistics, the average duration of life in men is at present 65·1 years and in women 66·4 years as compared with 38·4 and 40·7 during the period 1870–1879. The infant mortality, which was then as high as 22 per cent in males and 20 per cent in females, is to-day only 5 and 4 per cent respectively. During 1870–1879 only 7·6 per cent of Dutchmen reached the age of eighty years, whereas in 1931–1935 no less than 25 per cent reached that age. Holland has consequently the lowest mortality in Europe.

THE Council of the Royal Society of Arts offers a prize of £25 under the Thomas Gray Memorial Trust for an invention, publication, diagram, etc., which is considered to be an advancement in the science or practice of navigation, proposed or invented in the period January 1, 1934 to December 31, 1939. Under the same trust, a prize of £25 for an essay on "The Carriage of Dangerous Goods by Sea" is offered. Further information can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.2.

A RESEARCH scholarship of the value of £250 per annum and tenable for two years has been founded by the Wrought Light Alloys Development Association to encourage and facilitate research in the application of light alloys to ship construction. The scholarship will be administered by a Committee of the Institution of Naval Architects and it is hoped to make the first award in September 1939. Further information can be obtained from the Secretary, Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 119.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Glutamic Acid of Tumour Proteins

IN analysing tumour proteins, we[1] have isolated without exception partially racemized glutamic acid. However, Chibnall and co-workers[2] recently reported he isolation of optically pure $l(+)$-glutamic acid in our cases. These authors did not use the same method which we employed, but a different procedure which is excellent for the rapid and efficient isolation of natural glutamic acid from standard proteins.

Prof. Chibnall kindly sent us a copy of his preiminary note so that we could immediately carry out corresponding experiments.

The essential difference in the method of the British authors lies in a preliminary purification of the dicarboxylic amino-acids by precipitating them twice as the calcium salts[3] from 90 per cent alcohol. We have investigated the solubility of the calcium salts and found that the calcium-d,l-glutaminate is at least ten times as soluble as the calcium salt of the l-glutamic acid in 90 per cent alcohol. Although the pure racemic salt is relatively insoluble, the abovementioned difference can become very important through the tremendous influence of contaminating material in crude extracts, which is well known to all those who have isolated active principles from natural sources.

In our laboratory in recent months, Mr. A. M. Akkerman has investigated the 'ternary' system of d- and l-glutamic acid hydrochlorides in 20 per cent hydrochloric acid at 0° C. It was found that the d,l-hydrochloride is not a racemic compound but a racemic mixture (conglomerate); the solubility of which is exactly twice as great as that of the hydrochloride of $l(+)$-glutamic acid. Since we precipitate the crude glutamic acid by saturating the aqueous solution with hydrochloric acid at 0° C., we have also studied the solubilities in this concentration and found that, although both forms are less soluble, they showed quite the same difference in solubility.

In order to test the effects of these solubility differences upon the isolation, we have fractionated a mixture containing 75·5 per cent of pure l- and 24·5 per cent of pure d-glutamic acid according to the method of the British authors. We obtained 66 per cent of the l-glutamic acid originally present in the mixture in pure state ($[\alpha]_D = +31{\cdot}4°$).

The influence of accompanying substances is shown in the following experiment in which we used the hydrolysate from dried calf's embryo from which we had previously been able to isolate optically pure l-glutamic acid by our method. 600 mgm. of d,l-glutamic acid were added to the hydrolysate from 20 gm. of embryo tissue and the mixture fractionated according to the method of Chibnall *et al.* We obtained 1·16 gm. of pure l-glutamic acid hydrochloride ($[\alpha]_D = +31{\cdot}2°$). In a second experiment 700 mgm. of d,l-glutamic acid were added to 7·8 gm. of an alcohol precipitate which was prepared from the same embryo tissue in a previously described manner[1]. The fractionation, when done according to the method of the British authors, yielded 506 mgm. of pure l-glutamic acid hydrochloride ($[\alpha]_D = +31{\cdot}4°$).

Since the criticism might be raised that the depressions of optical rotation in our preparations of glutamic acid from tumours could be caused by analytically undetectable impurities having opposite rotation, we have attempted the isolation of the $d(-)$-glutamic acid. A resolution of the partially racemic glutamic acid by E. Fischer's[4] procedure was not practicable since benzoylation itself produces a partial racemization. We have therefore treated a partially racemic glutamic acid from Brown-Pearce tumours with fermenting yeast according to the method of F. Ehrlich[5] and were indeed able to isolate pure $d(-)$-glutamic acid ($[\alpha]_D = -31{\cdot}2°$).

In conclusion, it can be said that the method as it is employed by Chibnall *et al.*, in spite of very good yields obtained in the isolation of ***natural*** glutamic acid, appears not to be applicable for detecting the ***partial racemization*** of glutamic acid. In employing the method which we used, we recommend the inoculation with crystals of both enantiomorphs after saturation with hydrochloric acid, and further the recrystallization with the least possible loss of material. Details of our experiments will appear in the ***Zeitschrift für physiologische Chemie***.

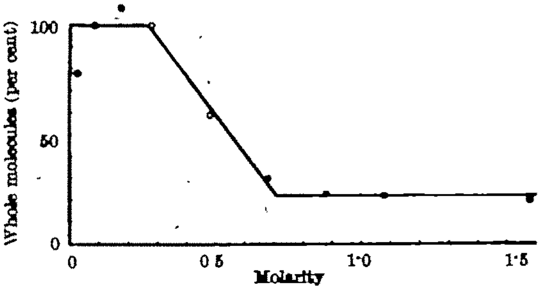
Dissociation of the Hæmocyanin Molecule

SEVERAL proteins are dissociated by a change of the hydrogen ion concentration, by adding amino compounds or salts to the solution [1, 2, 3, 4] and by exposure to various kinds of radiation[5].

The hæmocyanin molecule of *Helix pomatia* (molecular weight 6,700,000) may, upon a change of pH, dissociate into halves, eighths and sixteenths[6]. The reaction is reversible: the dissociation fragments recombine, if we bring the solution back to the original pH[6]. Certain amino compounds may also cause dissociation[1].

By means of the ultracentrifuge[1,2] we have investigated the influence of different types of salts and of a few non-electrolytes in acetate (pH 5·2) and in phosphate (pH 6·0) buffers of molarity 0·08. Well-defined sub-multiples ($\frac{1}{2}$, $\frac{1}{8}$, and $\frac{1}{16}$ of the original molecule) are obtained. The dissociation effect increases with the valence of the ions. The 1–1 valent sodium and ammonium chlorides both have the same effect: no dissociation occurs in 0·2 molar solutions, while in 1·0 molar 78 per cent of the hæmocyanin is dissociated into half-molecules. Nearly



the same effect is obtained for the 1–2 and 2–1 valent sodium sulphate and calcium chloride in 0·2 molar solutions (32 and 27 per cent, respectively), but the dissociation is different in 1·0 molar solutions, where sodium sulphate gives only half-molecules and calcium chloride eighths and sixteenths.

The dissociation effect of sodium chloride has been studied for a series of concentrations in acetate (pH 5·2) and in phosphate (pH 6·0) buffers of molarity 0·08, but in neither case were smaller components than half molecules obtained. In Fig. 1 the amount of whole molecules is plotted against the molarity of the electrolytes including acetate buffers. The dissociation reaction starts at the molarity 0·3 and ceases at 0·7, corresponding to a concentration of 22 per cent of whole molecules, after which concentration no more dissociation occurs. The same limiting value (22 per cent) is obtained with phosphate buffers of pH 6·0. When we use sodium chloride as dissociation agent, it is of interest to note that the reaction stops before all the whole molecules are dissociated (see graph). In solutions of molarity below 0·3 we have always got whole molecules.

The dissociation effect is smaller for non-electrolytes. The solutions investigated had a molarity of 1·0 in non-electrolytes, 0·2 in sodium chloride and 0·08 in phosphate buffer (pH 6·0). Glucose dissociated 64 per cent of hæmocyanin into half molecules, glycerine only 32 per cent. Urea (very often used as a dissociation agent for proteins) causes a dissociation of 58 per cent which is of the same order of magnitude as that for glucose; in the case of urea, however, 25 per cent of the dissociation fragments are non-uniform low-molecular compounds.

Reversibility has been observed in all cases where the dissociation had given only half molecules. The reaction is not completely reversible when the fragments obtained by the dissociation are smaller than half molecules.

It is shown from this and earlier investigations that dissociation of the hæmocyanin molecule is produced by a great variety of substances, and it follows that the effect is a general rather than a specific reaction associated with a special type of compound. Certain molecules or groups may have a stronger effect than others, but all types, whether ions or uncharged molecules, influence the dissociation of hæmocyanin.

Elimination of Administered Chloral Hydra
the Urine as a Test for Liver Functio

WHILE engaged in studying certain phase
toxicity of chloral hydrate to the organism,
made some observations regarding its urinary
tion in normal and liver-damaged dogs which p
to offer a great deal of information regarding
the most important functions of the liver,
its function of detoxication.

Chloral hydrate was one of the first hypnoti
to be used in therapeutics, and its action and
fate in the body have been worked out fairl
factorily. It is now generally agreed that ch
not broken down in the body but is redu
an alcohol which is conjugated with glucuro
and is excreted as the innocuous compou
chlorethylglucuronic acid (urochloralic or chl
acid). This method of excretion as urochlora
accounts for nearly the whole of the chlo
ministered, though some authorities think
small part of chloral may be excreted unchang
at most, minimal traces as inorganic chloric
chloroform[1]. The reaction is represented as f

$$CCl_3.CHO \rightarrow CCl_3.CH_2OH + CHO.(CHOH)_4.COOH \rightarrow CCl_3.CH$$
$$CO(CHO$$

Chloral Trichlorethyl alcohol Glucuronic acid Urochlor

The liver has long been recognized as ar
which plays an important part in the pro
conjugation with glucuronic acid. Recent res
by Hemingway *et al.*[2] on liver-kidney-lung-
limb perfusion experiments have proved
doubt that this conjugation always takes p
the liver and nowhere else. Under normal con
therefore, that is, when the liver is func
properly, any chloral that presents itself to t
cells will be almost completely coupled with glu
acid, an apparently unlimited supply of w
obtainable in the body from the metabolism o
hydrates or the glucogenetic amino-acids. If, h
the liver cells are damaged, due to the chronic i
of carbon tetrachloride for example, it is p
that this normal mechanism of conjugation
disturbed, the liver cells failing to mobilize glu
acid to the same extent as under ordinary con
If the administered chloral is not complete
satisfactorily conjugated, free chloral may m
appearance in the urine.

Working on this hypothesis, we have est
free chloral in 24-hour urine samples of
and liver-damaged animals after administra
200 mgm. per kilo. of chloral hydrate to do
in metabolism cages on a standard diet.
damage was brought about by the administra
1·5 c.c. per kilo. body weight of carbon tetra
on alternate days (every third day whenever S
intervened) for eighteen weeks according
method of Lamson and Wing[3]. The presence
chloral in the urine was estimated by the me
Friedman and Calderone[4] with the modificati
animal charcoal (1 gm. per 10 c.c. urine) w
ployed to decolorize completely the urine
starting the experiments. This treatment p
the masking of the final pink colour of the r
by the yellow pigment of urine. The resul
typical set of experiments are given in the fo
table.

It will be seen that, at least under the
mental conditions in our series, dogs with
damaged livers fail to conjugate chloral hydra

	Dog No.	Weight kgm.	Total excretion of free chloral hydrate in 24 hour urine after the administration of 200 mgm./kgm. of the drug. Figures given in milligrams				
			Days				
			1	2	3	4	5
Normal	4 5	5·5 4·7	*Nil Nil	Nil Nil	Nil Nil	.. ..	. ..
Liver Damaged	1 2	6·3 6·1	20 15	15 18	12 10	20 10	40 50

* 'Nil' indicates that either there is no free chloral hydrate in the urine or quantities less than 1 in 40,000 (0·025 mgm./c.c.) are present.

that degree of completeness characteristic of normal animals, thereby allowing significantly measurable quantities of free chloral to appear in the urine.

Although our series of experiments is small, we feel that this measure of chloral elimination after the administration of a known dose of chloral may be a valuable adjunct to the other methods of diagnosis of liver function, and an extended trial seems justifiable.

We are grateful to Colonel R. N. Chopra for giving us facilities and help in carrying out this investigation.

Nature of the Growth-accelerating Substance of Animal Tissue Cells

EVER since a technique for cultivating tissue cells *in vitro* has been developed, the isolation of the growth-promoting substances in the embryo extracts has been an important subject of research. Several important facts have been discovered during the attempts to isolate the growth-promoting substance of the chick-embryo juice tested on cultures of tissue cells of fowls. These investigations led in some respects to erroneous results, for example, the statement of the extreme lability of the active principles.

Experiments have long since indicated that the growth-promoting substances are unspecific as regards the animal species. New facts obtained lately are in favour of the assumption that one substance only is responsible for the activity.

In using beef embryo extract a most active growth-promoting fraction was obtained by isolating the nucleoproteins by using the method of Hammarsten[1]. When these nucleoproteins are dissolved in water by careful addition of sodium hydroxide and added to the culture medium of tissue cells a pronounced growth-acceleration takes place. With these substances, strains of tissue cells can be maintained for long periods of time. The ratio of phosphorus to nitrogen in the active fraction is about 12 per cent, much lower than that found by Hammarsten for the nucleoproteins of the pancreas, namely, 33 per cent. The nucleic acids found in the active nucleo-proteins belong to the thymonucleic acid type as well as the ribose nucleic acid type. The growth-promoting activity seems in the meantime to follow the fractions containing the ribose nucleotides. After reprecipitations of the nucleoproteins with glacial acetic acid in excess, the precipitate is most active and contains a relatively great amount of the ribose nucleotides and very little thymonucleic acid, whereas the non-precipitated substances remaining in solution contain relatively much thymonucleic acid and less ribose nucleic acid. These facts seem to agree very well with the statements of Jorpes[2], Levene and Jorpes[3] and lately of Caspersson[4] that the ribose nucleic acid was found in actively growing animal cells and thymonucleic acid in the resting cells.

The growth-promoting activity of the substance is destroyed after digestion with trypsin for a short length of time. Likewise the activity disappears after boiling for a few minutes. This indicates that the protein forms an important part of the active compound. Experiments have further shown that the active compound can be restored after coupling of two inactive components, the one thermo-resistant, the other thermo-labile—more likely the latter is the protein component. The active principle is probably of high molecular order since they are rather easily precipitated in the ultracentrifuge.

The Last Thousand Feet on Everest: Possible Bacterial Factor

PROF. YANDELL HENDERSON, in his article in NATURE of June 3, p. 921, emphasizes some of the difficulties facing the members of the expeditions to Mount Everest. The main handicap is the small amount of oxygen which can be breathed in per minute from such rarified air as exists at 29,000 ft. Prof. Henderson refers to my experiments on animals, which show clearly that mammals cannot be fully acclimatized to live under an oxygen pressure below 10 per cent of an atmosphere such as exists above 20,000 ft. These results have been confirmed by attempts of South American sulphur miners to establish permanent villages near this level. The highest permanent village is at 17,500 ft.[1].

The experiments with animals show also that even resting animals, which are not specially exercised or exposed to special muscular effort, cannot tolerate for an indefinite period the degree of oxygen-want in the tissues such as is suffered in an atmosphere containing less than 10 per cent of oxygen. From the symptoms in man and postmortem findings in animals, it may be concluded that all systems and organs are adversely affected by such severe anoxia and naturally the most important are the vital organs, namely, the cardio-respiratory system and the brain. Any attempt to assign supreme importance to any one organ is not likely to be successful, although the postmortem evidence indicates heart failure as the immediate cause of death. It seems that much more information regarding changes in the human organism at the last thousand feet might be obtained from clinical wards with patients suffering from severe oxygen-want.

Much has been written on various aspects of the physiological problems of high altitude, but above 20,000 ft. the problem enters the realms of pathology and clinical medicine. The physiology at the lower altitudes may therefore be of little help in elucidation of what is taking place in the human organism at excessive altitudes. Certain systems and organs have been very fully studied at the lower altitudes, and this tends to magnify their importance. However, one system, namely, the alimentary canal, has perhaps not received the attention it deserves.

In the course of some feeding experiments with white rats, evidence has been obtained that, under very low oxygen pressure, toxic substances accumulate in the gut. The toxic substances come from the food and from the tissues, but are probably oxidized under normal oxygen pressure and rendered harmless. Certain articles of diet, particularly certain proteins, seem to be most potent in producing these effects. By excluding these proteins from the diet, the resistance of the rats may be definitely increased. These adverse proteins include casein, egg albumin, meat and fish. Various other proteins have been investigated and zein, one of the proteins of maize, gives the best resistance, but a diet of whole maize alone is of no protective value. Adding zein to a maize diet improves the result, so that the zein appears to contain some favourable factor.

Certain amino-acids of the proteins have been tested separately, and adverse effects are obtained with histidine, cystine and arginine. Under bacterial action, histidine gives rise to histamine, which may cause collapse and shock. Collapse is a symptom also of severe anoxia. It is possible also that poisonous compounds of guanidine may arise from arginine. Resistance to oxygen-want is increased also in rats fed on diets containing adsorbents, such as charcoal, fibre or paper pulp, and kaolin. These may act by removal of toxic products from the contents of the alimentary canal. The most favourable foods for increasing protection against oxygen-want include carrots (the most protective), parsnips, beetroot, apples and bananas, all of which have a low protein content and also contain some fibre. As stated above, zein is the best of the proteins, with gelatin second, but not nearly so good. Starch, glucose, fat, vitamins and salts seem to be inactive—that is, they do not affect the result one way or the other, and therefore may be used in addition to the above more favourable articles of diet.

Undoubtedly, bacteria are responsible mainly for the adverse effects with most of the protein foods. Cats cannot tolerate the conditions at 14,000 ft., and this may be due to their protein diet. The variation in resistance observed in man may be due in part to variation in protein content of diet and to variation in bacterial flora in the intestine. The full details of the above experiments are being published elsewhere.

An Experimental Attack on some Proble Physiological Genetics

SINCE 1937, experimental work with *D*
melanogaster on two problems of physiologica
has been in progress in this laboratory.

(1) *Experiments on the development of th*
aristapedia (ss^a) *which transforms the bris*
antenna (*arista*) *into a tarsus*. In ss^a-flies
tion of the antennal disk starts two days ea
in normal flies[1]. Goldschmidt[2] therefore assu
at 2½ days of larval age an evocator which d
leg segmentation is present in the germ, and
in the proper stage of development will rea
stimulus by tarsus formation. In normal
undeveloped antennal disk will not reac
evocator. In ss^a-larvæ, however, the differ
of the antennal disk is speeded up and the
disk will react simultaneously with the le
starting tarsus segmentation.

If this explanation is correct, a compou
with different leg mutants should show th
effect on the legs also, on the antenna of
mutants influencing the arista should show
on ss^a. Confirmatory results were obtained
tests. Compounds of ss^a with *dachs* and
thickoid, mutants which influence the lengt
thickness of the legs respectively, showed
effects on the tarsus-like part of the anten
A compound of ss^a with aristaless, a mutant
the arista and influencing the scutellar bristle
no effect on the antennæ of ss^a, but its us
on the bristles could be observed. Transpl
of antennal disks were performed between
of ss^a and normal at different stages of l
from 2½ days to pupation. ss^a-Disks transpla
normal larvæ always developed into leg-li
tures; normal antennal disks transplan
ss^a-larvæ developed into normal antennæ wi
The negative results of these transplantatio
ments can probably be explained by the

s* is determined at a very early larval stage (2¼ days) prior to which successful transplantation is extremely difficult.

(2) *Experiments on the development of mutant wing characters.* With the help of an electrically heated needle, small defects were made during the developing young pupal wings. No significant effect could be detected on the degree of notched if *vg^no*-pupæ were operated on. However, a significant effect on the venation could be observed. If the defect was made on the basis of the wing at a pupal age of 12–18 hours, the distal cross-vein was mostly missing or reduced in the hatching flies. Pupal wings from *plexus* (*px*) and *net* stocks, mutants which show extra venation, were operated at the basis at the pupal age of 12–24 hours, and the hatching flies showed reduction in extra venation and the distal cross-vein. It was possible to get operated wings without any extra venation in *px* and *net* flies, while the other wing as unoperated control showed the *px* and *net* type clearly. Identical results were obtained after the defect was made by a cold needle.

Developmental studies indicated that the formation of the distal cross-vein and the extra venation takes place after the rest of the venation has been formed at 18–24 hours of pupal age. By operation at the pupal age of 12–24 hours, a general process of formation of veins is probably inhibited. The exact location of the defect does not seem to influence the degree and place of reduction of venation so long as the defect is placed in the proximal third of the pupal wing. Defects placed in the distal part of the wing result in destruction of distal parts without effect on the venation. Operations after 24 hours of pupal age result in local destruction of the tissue. Extreme changes in the shape of the wings were sometimes observed after operation. A detailed analysis of these studies will be published elsewhere.

A great part of these studies has been suggested by Dr. R. Goldschmidt. His advice and help are gratefully acknowledged.

Energy of High-Velocity Neutrons by the Photographic Method

FOR many years it has been known that after the development of certain types of photographic plates, the tracks of any heavy ionizing particles which have passed through the emulsion are represented by a succession of developed grains. Several investigators have examined the question of the precision with which the length of the track can be taken as a measure of the energy of the particle. Opinion on the question has been divided[1,2,3], and the method has not come into general use for nuclear problems though several investigators are using it for work on the cosmic rays. If the method could be made precise, it would have great advantages over expansion chamber technique in dealing with certain types of nuclear problem. Recently, having made experiments with Dr. Heitler on the heavy particles in the cosmic radiation by this method, we decided to re-examine the question of its precision in detail. In view of the importance of developing more powerful methods of measuring neutron and gamma-ray energies, the results seem to us to suggest that the method merits the serious consideration of those engaged in nuclear research.

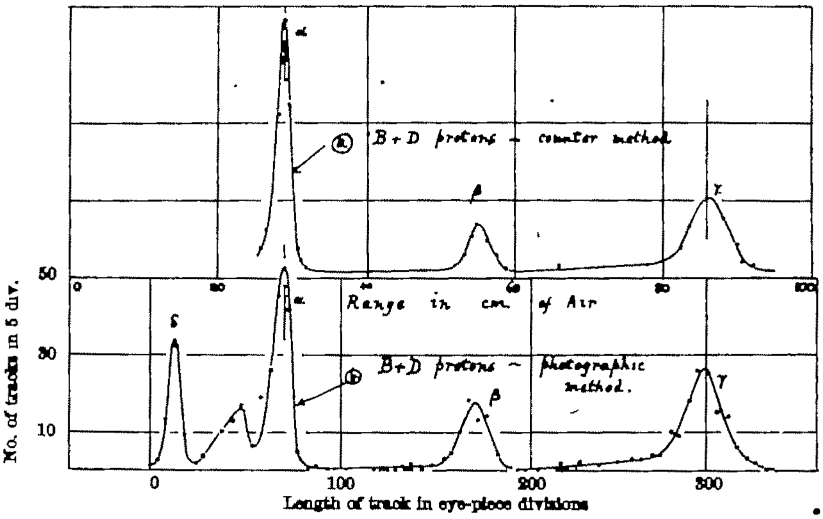

Fig. 1.

Curve (*a*), B + D protons by counter method. Curve (*b*), B + D protons by photographic method. Peak δ due to D + D protons.

We first passed protons from boron under deuteron bombardment, through a mica window and tangentially into an Ilford 'half-tone' plate, measured the length of the 'tracks' and drew the appropriate range-frequency curve. The corresponding curve obtained by counting methods[4] is shown in curve (*a*), Fig. 1, and our results in curve (*b*), the two scales having been chosen to make peaks 'α' and 'γ' coincide. It will be seen that the resolving power of the photographic method is comparable with that of the counting experiments for protons in this range of energy. The results shown in Fig. 1 enable us to calculate the stopping power of the emulsion and hence the range of particles in peak δ. This turns out to be 14·8 cm. of air and is evidently due to particles from the D + D reaction.

We next passed neutrons, from various light elements bombarded with deuterons, tangentially through similar plates and measured the lengths of the 'tracks' of the directly knocked on protons. We could thus determine the neutron energies in a way analogous to that employed by Bonner and Brubaker[5,6] using the expansion chamber technique. Our results for B + D neutrons and for Be + D neutrons are shown in Figs. 2 and 3, together with the results obtained with the expansion chamber. It will be seen that the photographic method has a resolving power considerably higher than that achieved with the expansion chamber.

We would direct particular attention to the great saving in labour which the photographic method

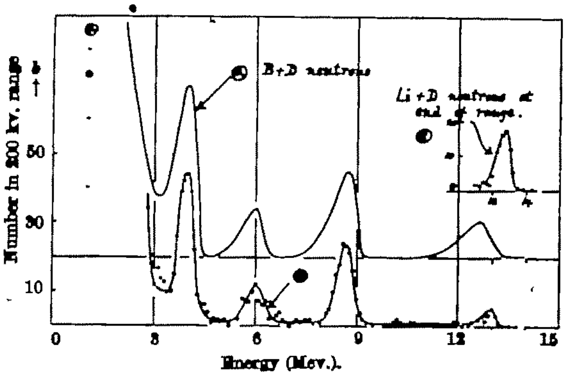

Fig. 2.

CURVE (a), B + D NEUTRONS BY EXPANSION CHAMBER METHOD. 1,000 TRACKS FROM 11,000 STEREOSCOPIC PAIRS.

CURVE (b), B + D NEUTRONS BY PHOTOGRAPHIC METHOD. 4 HR. EXPOSURE.

CURVE (c), END POINT OF ENERGY SPECTRUM OF NEUTRONS FROM LI + D BY PHOTOGRAPHIC METHOD.

affords. For the analysis of the energies of the neutrons from the Li + D reaction by the expansion chamber method, 20,000 stereoscopic pairs of photographs were taken from which 1,600 tracks were suitable for measurement. We have measured the energy distribution of these neutrons by the photographic method. The 3,000 tracks for the analysis are all contained in three square centimetres of an Ilford half-tone plate obtained in a single exposure of a few minutes.

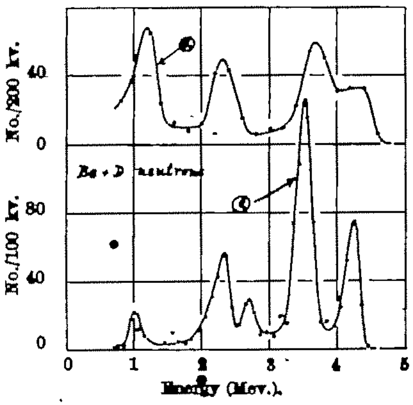

Fig. 3.

CURVE (d), BE + D NEUTRONS BY EXPANSION CHAMBER METHOD. 580 TRACKS FROM 3500 STEREOSCOPIC PAIRS.

CURVE (e), BE + D NEUTRONS BY PHOTOGRAPHIC METHOD. 20 MIN. EXPOSURE. 960 TRACKS. INTENSITY OF 1 MEV. PEAK LOW IN COMPARISON WITH OTHERS DUE TO IGNORING SHORTER TRACKS.

For experiments with neutrons the photographic method has the following important advantages: (a) It is equivalent to a continuously sensitive high-pressure expansion chamber. (b) It involves a minimum of material and does not give rise to disturbing scattered neutrons. (c) The photographic plate is small and can be placed very near the neutron source, with a corresponding gain in intensity. Many quantitative experiments with neutrons become possible, because of these advantages, which could not be seriously considered with the expansion chamber technique.

A complete description of the experiments in which we have examined the energies of the neutrons from all the light elements under deuteron bombardment and a discussion of further applications of the method will be published shortly.

Directional Distribution of the Hard and Soft Component of Cosmic Radiation

WITH a two-fold coincidence apparatus we have determined the intensity distribution of cosmic radiation in the north-south and east-west planes. The measurements were made in all four directions with zenith angles (δ) varied by 5° steps from the vertical to the horizontal. Every position was measured once with no absorber and a second time with 36 cm. lead between the counters. From the results it is possible to determine independently the directional distribution of the hard and of the soft component:

$$\text{Hard component: } R(\delta) \times 10^4 = 2 + 59 \cos^2\delta \quad (1)$$

$$\text{Soft component: } R(\delta) \times 10^4 = 3 + 27 \cos^{2\cdot5}\delta \quad (2)$$

The intensities are given in coincidences per cm^2/sec./unit solid angle. The following interpretation of these results seems to us justified.

The intensity of the hard component can be resolved into the intensity of two factors. The first represents the meson intensity, giving rise to a variation corresponding to $\cos^2\delta$. Assuming that the majority of the mesons are created at a height equivalent to about 8 cm. mercury pressure, below the top of the atmosphere, further that the number of the mesons created there with energies greater than E is given by

$$N = \text{constant}/E^\gamma, \quad (3)$$

with[1] $\gamma = 1\cdot8$, and that the meson intensity decreases chiefly through spontaneous decay, thus it will be a function only of the distance between the place where they have been created and the observer:

$$J = \text{const.} \int_{E_1}^{\infty} \frac{e^{-lE_0/\tau cE}}{E^{\gamma+1}}\, dE \sim \frac{\text{const.}}{l^\gamma}\,; \quad (4)$$

where τ is the life-time of the meson at rest ($\sim 10^{-6}$ sec.), E_0 is the energy of the meson at rest ($\sim 8 \times 10^7$ ev.), c is the velocity of the light, E_1 is the energy necessary to travel through the atmosphere ($\sim 2 \times 10^9/\cos\delta$ ev.), l is the distance of the observer from the place where the mesons were created.

A pressure of 8 cm. mercury in a vertical direction corresponds to a height of about 16 km. For more inclined directions we must take into consideration that a meson created at 8 cm. mercury below the top of the atmosphere will be in this inclined direction at a greater height from the observer at sea-level even when measured vertically. Thus for the distance measured in the inclined direction we obtain:

$$l = \frac{1}{\cos\delta}\left(16,000 + 14,620 \log \frac{1}{\cos\delta}\right) \approx \frac{\text{const.}}{\cos^{1\cdot3}\delta} \qquad (5)$$

(For greater elevations such as 11 km. use the barometric formula: $\Delta h = 14,620 \; (\log p_1 - \log p_2)$ metres.)

From (4) it follows that the intensity varies inversely as $l^{1\cdot8}$; together with (5) we may compute that the intensity must vary according to $\cos^{2\cdot3}\delta$; the experimental result being a $\cos^{2}\delta$ variation.

The second part of the intensity of the hard component consists of heavy particles created by neutrinos in multiple showers, the neutrinos themselves being a product of the meson decay[2]. It is, however, not quite excluded that neutrinos with magnetic moment are able to produce a coincidence with the help of two soft secondary electrons[3]. It can easily be seen that this part of the intensity should be invariant for every direction, since (1) the meson intensity can be taken as uniformly distributed over all directions at the place of origin; (2) the majority of the mesons are already disintegrated before they reach the apparatus, thus the number of the neutrinos will only slightly increase in more inclined directions through the number of those produced in further decay; and (3), on the other hand, the decrease in the number of the neutrinos in the inclined direction will also be negligible on account of their small absorption. This constituent of the intensity corresponds to the first term on the right hand side of (1).

In the case of the soft component, we can again distinguish two parts, the first consisting of electrons produced at the disintegration of the mesons, or cascade electrons created by them. This part of the intensity should vary according to the meson intensity, that is, with $\cos^{2\cdot3}\delta$; but we must also take into account that the probability with which the decay occurs in the region surrounding the apparatus is inversely proportional to the energy of the meson. Thus the intensity will be expressed now by

$$J = \text{const.} \int_{E_1}^{\infty} \frac{e^{-lE_0/\tau c E}}{E^{\gamma+1}} \frac{1}{E}\, dE \sim \frac{\text{const.}}{l^{\gamma+1}}\,; \qquad (6)$$

and we get finally from considerations analogous to those above that this part of the soft component should vary as $\cos^{3\cdot4}\delta$. The experimental results are in good agreement with a variation corresponding to $\cos^{3\cdot3}\delta$, the second term on the right hand side of (2).

The second constituent of the soft component furnishes again a constant intensity. It consists of electrons created by neutrinos. The same considerations as above hold also in this case; thus this part, corresponding to the first term in (2), should be invariant for all directions. We believe we have found here an explanation why the relative intensity of the soft component increases again not only for more inclined directions but also at very great depths[4].

So far as the reliability of the measurements permit, we are able to estimate the amounts of the different kinds of radiation observable at sea-level from the vertical direction. 65 per cent of the radiation consists of mesons, 30 per cent of electrons produced in meson decay or cascades initiated by them, 5 per cent of electrons and heavy ionizing particles created by neutrinos.

We wish to express our gratitude to the Hungarian Council for Natural Science, and the Hungarian Academy of Science for financial support.

Effect of an Electric Field on the Viscosity of Liquids

Prof. E. N. da C. Andrade and C. Dodd have described[1] their investigations of the effect of an electric field on the viscosity of a number of organic liquids. They state that they found an increase of viscosity of up to 60 per cent in polar liquids, while non-polar liquids showed no increased viscosity.

We would point out that work of a similar kind was performed by us in 1935[2].

We succeeded in showing that the increase of viscosity, which in some cases was more than 100 per cent, is due to the passage of the electric current through the liquid. Increased viscosity was also observed in non-polar liquids (benzene, hexane, carbon tetrachloride) when the latter had been artificially contaminated by the addition to the pure preparations of a few drops of the same liquid saturated with hydrochloric acid vapour, or of a few drops of acetone. In our opinion, this seeming increase of viscosity in a liquid under the action of an electric field is a purely hydrodynamic phenomenon due to the convection of a non-homogeneous liquid placed in an electric field.

[1] Nature, 143, 26 (1939).

[2] *Acta Physicochimica U.R.S.S.*, 5, 691 (1936).

We are sorry that the interesting paper of Sokolow and Sossinski, referred to in the above letter, escaped our notice, and we are very glad that our attention has now been directed to it. We agree that in it the authors clearly established a large effect of electric field on the apparent viscosity of polar liquids, and that the effect is accompanied by the passage of an electric current, both of which facts are among our observations. We think, however, that the method which Sokolow and Sossinski used, namely, a capillary of square cross-section, with the field applied to two opposite sides, is less precise than our disposition: we used a capillary of rectangular cross-section, with side ratio 1 to 50, and the potential applied to the long sides. In our case the field is uniform; in the other case, owing to differences of dielectric constant between liquid and glass, it is far from being homogeneous, which may be one of the causes of certain discrepancies which we have noted.

Owing to the fact that the upper limit of the fields used by Sokolow and Sossinski was 17 kv./cm., while our fields went up to 40 kv./cm., the Russian workers were unable to observe the saturation effect, namely, that the viscosity-increase becomes constant at high fields, which was one of the most striking of our results. This saturation is not accompanied by a saturation of current, which shows that the close relation between current and viscosity-increase suggested by Sokolow and Sossinski is unlikely to be correct. Their comparatively small number of frequencies and small range of frequency in the case of alternating potential, namely, the two frequencies 50 and 1,000 cycles/sec., as against our range of 0 to 10,000 cycles/sec., with determinations throughout the ranges, prevented them obtaining our effects in this part of the work. They have not calculated the effect which a low-frequency alternating current should have if at each stage static equilibrium existed between field and viscosity increase. If allowance for the variation of potential is made, we find that for 50 cycles/sec. the effect is the same as at a steady potential.

We believe that their explanation, that the effect is due to hydrodynamic convection, is not tenable in view of our results. It will not explain either the saturation at large fields or the lack of parallelism between current and viscosity increase. The conditions of Hofmann's experiments, on which Sokolow and Sossinski base their argument, are so different from those of our experiment that we do not think they are applicable. The explanation is also not in accordance with later experiments of ours which were not referred to in our letter in NATURE. In these we have carried out experiments with three different gaps, namely, 0·2 mm., 0·22 mm. and 0·28 mm., and have found that the effect at constant field, in terms of volts per cm. of gap, diminishes as the gap increases. This is one of the facts that led us to attribute the effect to the building up of comparatively rigid ionic layers on the opposite walls of the channel, layers which reach a limiting thickness at high fields. Assuming a constant thickness at saturation, we are able to explain quantitatively the influence of gap width on the effect.

A New Model of the Point Charge Electron and of Other Elementary Particles

WE wish to introduce a point charge electron which conserves a number of properties of the Lorentz electron and which can be taken over into quantum theory without any difficulties.

The Lorentz model of the electron (a charge e spread over a region of space of the order of a certain fundamental length l) is a satisfactory description of classical optics of wave-lengths $\lambda > l$. If $\nu^{-1} = \lambda \precsim l$, this theory contains the classical analogue of 'showers'. This can be seen from the equation of movement of the co-ordinates $q_a(t)$ of the centre of the electron. If the electric field is decomposed in an external field E'_a ($\alpha = 1,2,3,$) and the retarded field of the charge density $e\rho(x_a - q_a)$, this equation takes the form (if $\dot{q}_a = 0$*):

$$e^2(2l)^{-1}\ddot{q}_a + e^2\sum_{3}^{\infty} a_n l^{n-2}((\ddot{q})^{n-1}\ddot{q}_i + \;.\;\;.\;\;.\;) = (2/3)e^2\dddot{q}_a + \int dx^3 \rho E'_a \quad . \;\; . \;\; . \quad (1)$$

The term proportional to l^{n-2} superimposes on the periodic movement of frequency ν an additional
oscillation with the frequency ν/n. The
interpretation of the emitted radiation is the
effect and the simultaneous emission of n q
energy $h\nu/n$.

$e^2(2l)^{-1}$ is the mass due to the energy of the
and the (non-electrical) cohesive forces in the
We use the four-vector of the electrodynamic

Salaries of Scientific Workers

IN NATURE of July 1 there appears an advertisement asking for applications for a post under the Ministry of Agriculture and Fisheries, which requires a botanist with an honours degree and at least two years experience of research in systematic botany. The starting salary offered is £155 per annum. We would like to point out that this salary is not only incommensurate with the training required, but is also far below the normal salaries obtaining in Government departments for men of science holding equivalent qualifications.

In the same issue of NATURE there is an advertisement under the name of University College, Southampton, requiring the services of a research assistant of graduate standing who will receive free board and residence and a remuneration of £50 per annum. We also wish to direct attention to the salary offered, £250 a year, in the same advertisement for the post of superintendent of the Branch for Southern Rivers, Freshwater Biological Association.

REINET FREMLIN.
(Secretary.)

Association of Scientific Workers,
30 Bedford Row,

Points from Foregoing Letters

F. Kögl and H. Erxleben state that the method used by Chibnall *et al.*, although very suitable for the isolation of natural glutamic acid, appears not to be applicable for detecting the partial racemization of glutamic acid in hydrolysates from tumour proteins. The presence of racemic glutamic acid in tumour proteins was shown by the isolation of the *d*-form.

S. Brohult and S. Claesson have investigated the influence of different types of salts and of some nonelectrolytes on the dissociation of the hæmocyanin molecule. The dissociation reaction, usually reversible, seems to be of a general type, as it is caused by ions as well as by uncharged molecules.

B. Mukerji and R. Ghose suggest a new method for measuring liver function. Under ordinary conditions, no free chloral appears in the urine of dogs given this substance. When the liver is damaged by the chronic administration of carbon tetrachloride for 18 weeks, appearance of free chloral in significant amounts following the administration of the drug was observed in the urine.

Albert Fischer states that the growth-promoting principle of embryo extract is found in the fraction of nucleoproteins isolated by the method of Hammarsten. The ratio of phosphorus to nitrogen is rather low. The active fraction contains ribose nucleotides and very little thymonucleic acid. The activity is destroyed after digestion with trypsin and after boiling for a few minutes. Restoration has been possible after coupling of two inactive components. Precipitation in the ultracentrifuge indicates that the active principle is of high molecular order.

Evidence has been obtained with white rats by J. Argyll Campbell that under very low oxygen pressure toxic substances accumulate in the intestine. Certain proteins, for example, casein, egg albumin, meat and fish, in the diet give adverse effects. Certain amino acids, for example, histidine, arginine and cystine, also give adverse effects. Bacteria are held responsible for the toxic substances.

Werner Braun reports on some experimental work in physiological genetics. Using the fruit fly as material, he records experiments on the development of the mutant responsible for the transformation of the bristle on the antenna into a tarsus, and on the development of mutant wing characters.

C. F. Powell and G. E. F. Fertel have developed a technique for the determination of the energy of protons and neutrons by measurement of tracks made by these particles on special photographic plates. For many investigations the method has great advantages over the expansion chamber technique.

J. Barnóthy and M. Forró find that the results obtained by measuring the directional distribution of the soft and hard component of cosmic radiation can be explained by assuming that the radiation at sea-level consists of 65 per cent mesons, 30 per cent electrons produced in meson decay, and 5 per cent of electrons or heavy ionizing particles created by neutrinos, this part of the intensity being invariant for all directions.

S. Sossinski points out that he and Sokolow published in 1936 work in which they showed that an electric field has a great effect on the viscosity of polar liquids, a fact to which attention was recently directed by Andrade and Dodd, and suggests a hydrodynamic explanation. E. N. da C. Andrade and C. Dodd, in reply, regret that they overlooked the paper in question, and point out that their work goes much beyond that of Sokolow and Sossinski. They suggest that the effect is due to the building up of comparatively rigid ionic layers on the opposite walls of the channel.

E. C. G. Stueckelberg derives an expression for a point charge electron which can be taken over into quantum theory.

RESEARCH ITEMS

Biology of Cerambycid Beetles

C. F. C. Beeson and B. M. Bhatia have published an article "On the Biology of the Cerambycidæ". in which they present data collected during twenty-four years on the food plants, distribution, life-cycle and other biological features of 350 species of this family of beetles from India, Burma and Ceylon (*Ind. Forest Rec.*, Ser. Entom., 5, No. 1 ; 1939). The total number of species of Cerambycidæ, or longicorn beetles, known to occur in the Indian region is 1182. It appears that the sal (*Shorea robusta*) is the tree which supports the largest number of species, some 37 different Cerambycidæ being known from it. The beetle *Stromatium barbatum* is recorded to have no fewer than 311 different food plants, which indicates a very unusual range of polyphagy. The food plants of at least 250 species of these insects have not been previously published, and a total number of 568 species of Indian trees, shrubs and woody climbers is now known to be attacked by one or more kinds of Cerambycids. *Hoplocerambyx spinicornis* is potentially the most injurious forest insect in India. This is partially due to its liability to cause bad epidemics among the sal forests. Even a small outbreak of this insect, affecting eight square miles of forest in the United Provinces, resulted in 45,000 trees being killed, representing nearly a million cubic feet of timber. The most serious epidemic was estimated to have attacked about seven million trees before it was checked. The new data given for the biology, etc., of this species are more complete than for any other : for many of the species little more than the host tree and the locality are at present available. It is mentioned that sun-loving or diurnally active species may frequent the foliage and flowers of trees without any of them breeding as larvæ in the wood or feeding as adult beetles on the foliage or other parts of such trees.

Ring Spot Disease of Lettuce

THE fungus ***Marssoniana Panattoniana*** in epidemic form rapidly destroys lettuce seedlings and may also destroy older plants. Even a mild attack causes browning and perforation of the leaves which give rise to the name 'ring spot'. The disease is an important one in England, and has at various times caused considerable damage in Europe and America. Winter lettuce is the crop most affected, the disease being rare on plants grown under glass or planted out in spring. Experiments carried out over three years by Greta B. Stevenson at the Biological Field Station of the Imperial College (*J. Pom. and Hort. Sci.*, 17, 27 ; 1939) have shown that the disease is readily transmitted by seed. Diseased plants gave apparently good seed which, however, under suitable conditions produced a heavily infected crop. On the other hand, sprayed and segregated mother plants gave seed which produced healthy plants where commercial seed gave valueless crops. The disease may also be contracted from the remains of a previous infected crop, though such remains normally lose their infectivity after about eight months. A similar fungus was found on a common weed (*Crepis capillaris* Wallr.) growing
near diseased plants, and it is believed that tl
be a source of infection. Sixteen commercial v
of lettuce were all found to be equally suscep
ring spot. Reduction of the disease was affe
spraying the seedlings with Bordeaux r
(3 : 6 : 50) and by treatment of the seed
filtered 10-per cent solution of bleaching powd

Chemistry and Genetics

Chromosomes of the Sawflies

THE characteristic diploid chromosome number in the Tenthredinidæ, the sawflies, is sixteen, although in Claudius and a few other species allied to this genus the number is twelve. A. D. Peacock and Ann R. Sanderson have investigated the cytology of another sawfly, *Thrinax macula* Kl. (*Trans. Roy. Soc. Edin.*, 1939), in which the diploid number is fourteen as found in the blastoderm, follicle cells, oogonia, oocytes and polar nuclei. This species is a female-producing parthenogenetic one in which, however, rare males sometimes make their appearance. Some of the latter were fortunately found and they appear to be haploid with a chromosome number of seven. During the maturation of the egg only one non-reductional division takes place in which there is neither synaptic pairing nor tetrad formation. The diploid number is presumably maintained in this species by the omission of synapsis, as is probably the case in the majority of parthenogenic animals in general. It is to be noted, however, that two maturation divisions do occur in some female-producing parthenogenetic sawflies. During spermatogenesis the first maturation division is abortive and the second is equational, as is commonly found in the Hymenoptera.

Chromosome Rearrangements in Drosophila

B. P. Kaufmann (*Genetics*, **23**, 154; 1938; **24**, 101; 1939) and B. P. Kaufmann and Ruth C. Bate (*Proc. Nat. Acad. Sci.*, **24**, 368–371) have analysed some chromosomal abnormalities in the progeny of X-rayed *Drosophila melanogaster*. One individual showed a duplication *abcdgfeefgh* in the nature of a 'reversed repeat'. This is shown to have arisen from the breakage and reunion of two sister chromatids derived from one paternal chromosome. Complex configurations were found. One configuration involved ten breaks and attachments, of which five were in one chromosome arm. Another showed that both chromatids of the duplicated section had been broken at two similar loci accompanied by a third break in each of the chromatids which had occurred at different loci.

Position Effect

HAIRY wing (*Hw*), a well-known and much used dominant character near the distal end of the *X*-chromosome of *Drosophila melanogaster*, has been shown by M. Demerec and M. E. Hoover (*Genetics*, **24**, 68, 271–277; 1939) to be due to a duplication of a single band of a salivary gland chromosome. This band is known to be associated with achæte (*ac*), which reduces the dorso-central bristles. Further, as in Sturtevant's Bar case, it is shown that when two bands are represented on one chromosome they have a greater effect than if they were distributed between two chromosomes. Unfortunately, no case of crossing-over between the two bands has yet been observed. This may probably be due to the fact that crossing-over is normally low in the region *y–ac* where *Hw* is placed.

Heterosis

L. C. LUCKWILL (*J. Genet.*, **37**, 421–439) has investigated the stage in the life-cycle of hybrid tomatoes at which heterosis is manifested. There was little correlation between heterosis in the seed and in the mature plant. In some hybrids heterosis was present in the shoot primordium on the 16th day and persisted until the 145th day, while in other hybrids heterosis arose subsequent to the 16th day. The author considers that in intraspecific hybrids heterosis may be dependent on complementary size determining genes as visualized by Jones. For interspecific hybrids, however, he produces evidence to support East's hypothesis.

Structure of South-east England

DEFINING South-east England as the region lying south and east of the main chalk escarpment between Dorset and The Wash, S. W. Wooldridge and D. L. Linton have written a closely reasoned monograph on the development of its structure and relief ("Structure, Surface and Drainage in South-East England". Institute of British Geographers Publication No. 10. 1939. 12*s*. 6*d*.). The broad lines of the structure of this area are well known, but the two authors have added much detail and traced in lucid fashion the genetic development. They begin with the early Palæozoic floor. Particular interest is attached to the concealed junction of the Armorican and Caledonian structures which runs beneath the Lower Thames Valley. Southwards the cover rocks show competent folding and northwards only gentle flexuring. After the emergence of the chalk floor, a full cycle of erosion ran its course and the greater part of the area lost its upper divisions of the chalk. The mid-Tertiary flexures south of the Thames and the mid-Tertiary foldings and the subsequent production of the late Miocene and early Pliocene peneplain are then traced. The invasion of the Pliocene sea and the emergence of the Pliocene sea-floor followed, and the lower Thames is shown to have had a course well north of its present channel. Then came the effects of the Chiltern and eastern ice sheets and the general subsequent uplift of the area. The monograph is well illustrated by maps and diagrams.

Range of Possible Existence of Stoneley Waves

THIS problem has been studied by K. Sezawa and K. Kanai (*Bull. Earthquake Res. Inst.*, Tokyo Imp. Univ., **17**, Part 1, 1–8; March 1939). First they obtained the velocity equation for waves of this type which are particular forms of Rayleigh waves, and from this equation calculated the velocity of transmission in the critical conditions of the equation which allow waves of this type to exist. From tables and graphs in two limiting cases of Poisson's ratio, it is seen that Stoneley waves exist within a narrow range of μ'/μ for every ratio of ρ'/ρ. The authors point out that this feature is remarkable, particularly when the ratio of ρ'/ρ is nearly unity, at which condition Stoneley waves could not exist unless Wiechert's condition, $\rho'/\rho = \mu'/\mu$, be almost satisfied. On the other hand, when the ratio of ρ'/ρ is relatively small, say less than $0{\cdot}5$, or relatively large, say greater than 2, the range of μ'/μ in which Stoneley waves exist is relatively wide, Wiechert's condition being then rather unimportant. The greater the ratio ρ'/ρ, the greater the ratio μ'/μ for the real existence of the waves. The velocity of transmission of the waves is independent of the wave-length, that is, they are not dispersive. It is likely that in between the critical values the velocity of transmission is less than either one of the velocities of distortional waves in both media. The waves are found not to exist for the range $0{\cdot}563 > \mu'/\mu > 0{\cdot}4927$, the corresponding velocities of transmission ranging between $\sqrt{\mu/\rho}$ and $0{\cdot}9926\sqrt{\mu/\rho}$, where ρ, ρ', are the densities and μ, μ', the elastic constants of the adjacent media.

Structure of Vitamin B_6

VITAMIN B_6 is that factor of the vitamin B complex which prevents or cures an acrodynia-like dermatitis in young rats. If factor 2 is added to the usual thiamin and riboflavin supplement, vitamin B_6 not only produces a cure of the dermatitis but also a stimulation of growth. It has also been found that a severe microcytic hypochromic anæmia developed in puppies when the rat antidermatitis factor (vitamin B_6) was apparently the only missing component of the diet, and the anæmia was cured by the addition of this factor to the diet. The constitution of vitamin B_6 has now been established by a group of workers in the research laboratory of Merck and Co., Inc. (*J. Amer. Chem. Soc.*, 61, 1237–1247; 1939), whose results confirm those obtained by Kuhn and co-workers published this year. The vitamin was isolated from rice bran as the hydrochloride $C_8H_{12}O_3NCl$ of a base $C_8H_{11}O_3N$ (m.p. 160°). The methyl ester of vitamin B_6 was oxidized to a lactone and a dibasic acid. The acid was shown to be 2-methyl-3-methoxypyridine-4, 5-dicarboxylic acid and vitamin B_6 to be 2-methyl-3-hydroxy-4, 5-(hydroxymethyl)-pyridine. The 3-cyano-4-ethoxymethyl-6-methyl-2-pyridone was made from ethoxyacetylacetone and cyanoacetamide. This 2-pyridone derivative was used for the synthesis of the lactone of 2-methyl-3-methoxy-4-hydroxymethyl-5-carboxypyridine and the 2-methyl-3-methoxy-4, 5-pyridine dicarboxylic acid. This lactone and this acid were found to be identical with the lactone and dibasic acid obtained by the oxidation of the methyl ether of vitamin B_6, and the latter was thus proved to be 2-methyl-3-hydroxy-4,5-di-(hydroxymethyl)-pyridine. A complete synthesis of vitamin B_6 from ethoxyacetylacetone and cyanoacetamide was accomplished. The synthetic vitamin B_6 hydrochloride was shown to be identical with the natural product. A single dose of 100 gamma of the synthetic vitamin B_6 hydrochloride gave a curative effect which paralleled that of the natural vitamin B_6.

Metabolism of Chloronaphthalenes

R. V. Cleary, J. Maier and G. H. Hitchings (*J. Biol. Chem.*, 127, 403; 1939) have studied the metabolism of a mixture of polychloronaphthalenes. The substance was found to be absorbed completely when given in olive oil solution to albino rats in doses up to 15 mgm. per day. No significant storage of the material could be detected in lung, liver, skin or kidney, nor was any significant amount excreted in the urine. Both the rat and dog apparently were able to remove and excrete the chloride promptly. A rise in the urinary ethereal sulphate fraction, but no significant change in the neutral sulphate excreted, was noted following chloronaphthalene feeding in the dog.

Testing of Electric Fuses

IT is of considerable importance to know the time necessary for the melting of fuses upon the occurrence of an electric short circuit. This time must be short enough to prevent damage to the apparatus or to the lines in series with the fuse, before the fuse has melted. It is particularly important in the cases of

CYTOGAMY: A NEW SEXUAL PROCESS IN JOINED PAIRS OF PARAMECIUM CAUDATUM

By Dr. Ralph Wichterman, Temple University, Philadelphia

TWO sexual processes have been described for Paramecium in which three micronuclear (pre-mic) divisions lead to synkaryon formation. One ocess, called conjugation (cross-fertilization), may defined as the temporary union of two individuals volving three micronuclear divisions, *nuclear exange* and the establishment of a new synkaryon each conjugant.

The second process, called autogamy (self-fertilizaon) was described by Diller[1] for *Paramecium aurelia* occurring in *single* animals only. Here three icronuclear divisions lead to the formation of metic nuclei which fuse and form a synkaryon in e single animal.

I have observed a third sexual process in joined aramecia which appears to be intermediate to true onjugation on one hand and autogamy on the her. It resembles conjugation since two animals in together along their oral surfaces as in conjugaon, but there is *no nuclear exchange* between e members. Instead, the three micronuclear ivisions lead to the formation of the gametic nuclei, ut a synkaryon is established in the *same individual* s in autogamy. I am therefore proposing a new erm, *cytogamy*, for this phenomenon as distinct from utogamy in single individuals and true conjugation nvolving a nuclear transfer in joined pairs.

A new method of studying *living* joined *Paramecium udatum* with a view of obtaining a better undertanding of the problem of sexuality and nuclear ehaviour was begun two years ago. By using recently developed precision micro-compression hamber, it is possible to observe in the living conition the behaviour of nuclear phenomena over a airly long period of time. In addition, accurate ime relationships can be determined during the nion. In this preliminary note, the method and bservations may be stated briefly as follows:

With a micro-pipette, a single pair of recently oined paramecia is removed from a pedigree ulture, placed in a small drop of culture fluid on he circular glass slide of the micro-compressor and tudied at approximately 26° C. Extremely fine djustments to within a few microns make it possible o prevent gradually the joined paramecia from piralling between the two pieces of glass. When he joined animals move slowly, detailed observations may be made. In this manner, the divisions of the micronuclei and their behaviour have been seen and photographed on 35 mm. and 16 mm. motion picture film. The behaviour of the micronuclei in cytogamy closely parallels the described accounts of conjugation up to the stage of pronuclear exchange.

Cytogamous paramecia, which are considerably smaller than typical vegetative ones, are very insecurely attached to each other at their anterior ends at the beginning of the process. They can be separated very easily in the first hour or two of union. After they have been joined firmly, there is a progressive dedifferentiation of the ingestatory structures which appear to pass into a sol state. The micronucleus of each cytogamont leaves its place near the macronucleus and then gradually increases in size. This enlargement takes approximately 4–5½ hours, while the subsequent anaphase and telophase stages require only about 18 minutes.

The 'crescent' prophase stage and long anaphasic telophasic separation spindle, so characteristic in accounts of conjugation, is shown clearly. The swollen part at the centre of the separation spindle is passed into the cytoplasm (micronuclear chromatin extrusion) where active cyclosis moves this fragment about until it ultimately degenerates. Each product of the first micronuclear division enters into the second where again two long spindles in each individual are visible. This second division requires 50 minutes for completion from the time the first division products are formed. The anaphase and telophase stages take place still more rapidly, requiring only nine of the fifty minutes.

Micronuclear products, even while dividing, are moved about in the streaming protoplasm. Degeneration of three of the four products of the second division is observed. The remaining product enters into the third pregamic division, resulting in the formation of two pronuclei in each individual. The pronuclei of each single individual of the joined pair are seen to fuse and form a synkaryon in the *same individual*. No evidence has been obtained to indicate a transfer of pronuclei as is supposed to occur in conjugation.

To simulate normal conditions, the cytogamous paramecia are allowed to spiral freely except during those stages when critical observations are made. In fact, the joined paramecia may be removed from the small drop of culture fluid in the chamber and placed in a larger volume until a further observation is to be made, at which time they may be replaced in the chamber. On the other hand, the entire process may be observed in the micro-compression chamber. Since practically all the other stages of micronuclear behaviour can be verified with stained slides of joined paramecia, it seems very unlikely that the stage of nuclear transfer would be the only one affected by the relatively slight amount of compression to which they are subjected at certain times.

One is struck by the non-synchronous character of the nuclear activity in the individual members of a pair; that is, one member may show a nuclear stage definitely more advanced than that of its mate. This condition is seen occasionally. Recently Penn[2], using stained slides, also observed this phenomenon in a reinvestigation of the cytology of conjugation in *P. caudatum*. Although he believed he was studying conjugation, it appears very likely from his account and photographs that cytogamous individuals were seen instead. In such joined individuals, where the micronuclear divisions are out of phase with each other, the conclusion that there is a simultaneous pronuclear transfer which characterizes conjugation seems irrational.

After the individuals of a pair separate along their margins, a thin, clear, highly elastic strand holds the organisms* together. This strand, which finally breaks, consists of the fused and stretched apices of the paroral cones. Joined individuals may remain together for about 13¼ hours at 26° C.

Diller writes, "Whenever conjugation is found in a culture, autogamy is likely to be taking place simultaneously; and conversely, when no conjugation is occurring in a culture, autogamy is unlikely to be seen". He says further that autogamous animals were "sticky" and more likely to stick to the wall of the pipette during transfers. It is very reasonable to suppose that Diller may have been observing pairs of individuals undergoing cytogamy instead of pairs undergoing conjugation as he believed.

Before this present work was undertaken, I was impressed by not being able to find clear and convincing cases of nuclear exchange after studying many slides of fixed and stained 'conjugating' paramecia from different sources. I believe now that I may have been studying cytogamous individuals and not true conjugants. The fact that a dividing third pregamic or maturation spindle presses against the contiguous membranes of joined paramecia is not evidence enough to enable one to infer pronuclear exchange, even though the membranes may appear to be stretched. It may indicate, however, that in a cytogamont, the membrane in this reg paroral cone is very elastic.

In all my pedigree cultures, individ joining in cytogamy are never strongly a each other as is so strikingly demon Sonneborn's[3] sex reaction of paramecia. gamous union, they become rather f insecurely joined in the beginning of th mass pedigree cultures left standing in the for approximately seven days after usually demonstrate this type of union wit cytogamy. Perhaps cytogamy takes plac strains of *Paramecium* and true conjug when diverse strains are present.

Finally, my observations[4,5] have led me the work of others where a transfer of p *presumed* to occur in "conjugation". Th may be raised as to how often joined c individuals in a culture of Paramecium (or ciliates) have been mistaken for true conj investigators.

THE MUSEUMS ASSOCIATION

JUBILEE CONFERENCE AT CHELTENHAM

AT its annual conference held at Cheltenham in the week commencing July 2, the Museums Association celebrated the fiftieth anniversary of its foundation. In his presidential address, the Right Hon. Viscount Bledisloe appropriately dealt with the state of museums fifty years ago and with the progress that has been effected in the intervening years. Speaking of the needs of the future, he suggested that at least one open-air folk museum might be established in England, for example, in the Forest of Dean. He also directed attention to the lack of any English museum illustrating agriculture.

In addition to a gracious message from its patroness, Her Majesty Queen Mary, the Association received many messages of greeting and congratulation from kindred societies, including the International Museums Office, the American Association of Museums, and the Internationaler Museenverband.

On behalf of the Standing Commission on Museums, Sir Albert Seward read an address prepared by Sir Evan Charteris; and an address from Mr. Arundell Esdaile, president of the Library Association, was also read.

Conveying the congratulations of the Royal Society of Arts, Lord Amulree, its chairman of Council, delivered an address on the museum as an aid to the encouragement of arts, manufactures, and commerce, in which he put forward the attitude of the Royal Society of Arts to the question of museums. He recalled that the Society held in 1760 the first important exhibition of contemporary art in England, and in the following year what was probably the first industrial exhibition in the world. The latter exhibition gave rise to "the Society's Repository or Model Room", which could be claimed a industrial museum. The part played by t in the establishment of the Science Muse Kensington, and its subsequent activiti field were also discussed.

Prof. Anders Bugge conveyed greeting Norwegian Association of Museums, and Chubb and Mr. A. R. Penfold those of African and Australian and New Zealand As

Sir Robert Witt, chairman of the Nat Collections Fund, gave an account of the r that organization to the work of museum galleries.

One of the most important features of ference was an address by the Right Hon. I Warr, president of the Board of Edu "Museums and Education", in which he the great value of local museums in te right use of leisure, and in assisting develop the practical and realistic side of sc The Board of Education is prepared applications for grants from local educatic ties for museum activities specially arrang benefit of school children. Museums dese for all the trouble they are taking in helpi to-day, and encouragement towards st activities in the future.

An address which was received by all with the very greatest enthusiasm was tha His Excellency Don Salvador de Madariaga of the International Museums Office, on and World Peace". To visit an art museu a Velasquez, a Watteau, or a Constable is ciate the true character and inner thoug anish, French, and English nations. Art museums of great importance in educating the emotions d in promoting a feeling of human unity. Their licy might be to bring out that power of man over tter which is opposed both to the exploitation of verty and to the use of power over other men.

Speaking on "The Function of Natural History seums", Dr. W. E. Swinton, of the British seum (Natural History), referred to the great ilities for education in museums, but made a plea r the education of the adult as well as the child. great deal of the so-called educational work done museums is not related to their true function and uld equally well be carried out by other institutions. e great value of natural history museums is to ing the visitor back to the basis of things. Dr. inton made a plea for simpler series of exhibits th fewer specimens (and preferably some that uld be handled), and with clear explanatory labels.

A private meeting of the Association discussed air id precautions in museums, and it is understood at the recent Government handbook on this bject received some criticism.

Among the other discussions held during the onference was one initiated by Dr John Rothenein, director of the Tate Gallery, entitled "Towards Policy for Art Galleries", and a long discussion on r. S. F. Markham's "Report to the Carnegie rustees on the Museums of the British Isles".

In the course of various excursions, the long barrows of Belas Knap and Notgrove were inspected, as were the Roman Villa at Chedworth and the new Corinium Museum at Cirencester; also the Saxon Church at Deerhurst and Tewkesbury Abbey. Gloucester Cathedral and the Gloucester Museums were also visited. Garden parties were given by Viscount Bledisloe at Lydney Park and by Mr. Robert Holland-Martin at Overbury Court.

The Conference Exhibition was one of the largest ever held. As well as various trade stands, it included a collection of photographs by the Royal Institute of British Architects to illustrate contemporary museum architecture; examples of Cotswold crafts; an extensive display of material from the Leicester City and County Schools Loan Department of the Leicester Museum; two new loan cases prepared by the Victoria and Albert Museum and three by the Yorkshire Federation; and an exhibit by the Reading Museum of modern methods of casting.

At the annual meeting of the Association, honorary membership was conferred upon the Right Hon. the Earl of Harewood, M. E. Foundoukidis, Dr. E. E. Lowe, Mr. T. Sheppard, and Mr. William Wyndham, and the first diplomas under the Association's training and examination scheme were presented.

The next conference of the Association will be held at the Liverpool Public Museums in July 1940.

ASSOCIATION OF SHORT-CIRCUIT TESTING AUTHORITIES

DURING the last ten years, owing to the increase in the size of electrical power generating tations and of the machines they employ, together rith the greatly increased voltages used for distribuion, very difficult problems in switchgear technique nd design have come to the front, which make it ecessary to make a practical test of modern circuitreakers of an unprecedented size. During an ccidental short circuit, enormous currents may be enerated, and if the circuit be not broken by suitble switchgear, great damage may be done to very xpensive cables and generators. After intensive esearch, switchgear manufacturers realized that they nust provide themselves with testing facilities on a very much larger scale than was hitherto in existence, n order that the apparatus manufactured should meet the new conditions satisfactorily, performing its functions, to the specified ratings, to the satisfaction both of user and manufacturer alike. The design of circuit-breakers has now become a specialized science.

The manufacturers have therefore erected high-power testing stations, fully provided with the most up-to-date equipment for the testing of circuit-breakers, fuses, reactors, transformers, etc. Without these facilities, manufacturers would have found it practically impossible to comply with the demands imposed upon them by the rapidly changing conditions in the supply industry. The owners of these high-power short-circuit testing stations soon realized that their separate endeavours would be of much greater benefit to the industry if the results of their experience and research in this highly specialized field could be pooled, and this resulted in the formation of the Association of Short-circuit Testing Authorities (ASTA). It is a company limited by guarantee and not having a share capital. In order to comply with the Board of Trade requirements, the articles of association provide (*a*) that the income and property of the Association shall be applied solely to the promotion of its objects as specified in a published memorandum, and (*b*) that no addition to the regulations contained in the articles of association can be made without the permission of the Board of Trade.

We have received from the head office of the ASTA, 36 Kingsway, London, W.C.2, an interesting illustrated publication giving general information on the short-circuit testing and certification of electrical apparatus. The names of eight of the largest electrical companies in England, which form this Association, are given. Prior to the formation of ASTA, individual owners of short-circuit testing plants had tested and certified the products of some manufacturers who had no testing facilities of their own. Other manufacturers held the view that there should be a national testing plant under the control of the National Physical Laboratory and a suggestion to this effect was made to the Home Office. The Department of Scientific and Industrial Research was asked to consider this suggestion, and, in reply to a questionnaire issued by the Department, the owners of short-circuit testing stations directed attention to the following points:

(1) That there are in existence or under construction short-circuit testing plants of a greater capacity than exist in any other country in which switchgear is being manufactured.

(2) That most of the manufacturers who have no testing plants would be satisfied if they could obtain

testing facilities for circuit-breakers of a maximum capacity of 250 million volt-amperes with a voltage limit of 11 kilovolts.

(3) That if the existing testing stations could place the necessary facilities at the disposal of the D.S.I.R., this seemed to be the most economical method of meeting the situation.

The Department saw the advantage from the national point of view of utilizing the existing facilities, and it has now been agreed that the ASTA will collectively place at the disposal of the D.S.I.R. facilities equivalent to one 'test bay' a year for testing circuit-breakers up to the agreed limits of capacity and voltage, and, further, that the D.S.I.R. will appoint a resident officer at any test plant where testing is being carried out, with a view to certification of the results by the National Physical Laboratory. These arrangements will enable the N.P.L. on request to undertake, supervise and certify the results of tests of switchgear manufactured by n members of ASTA. Manufacturers wishing to ha short-circuit tests carried out by the Association w. a view of obtaining a certificate from the N.P. should apply in the first instance to the director of t National Physical Laboratory, Teddington, Middles

The testing stations are at Hebburn-on-Ty Trafford Park (Manchester), Stafford, and Witt Birmingham. The generators are of unusual desig capable of short-time rated outputs in excess of t normal outputs of the largest power stations, a mechanically constructed to withstand the stres resulting from repeated short circuits. The priva of all tests is rigidly ensured, but a reasonable numb of persons nominated by a client are welcome witness them. Members of the Association do considerable amount of research work, not only f manufacturers, but also in the general interests the electrical industry.

'TIME-OF-DAY' ELECTRIC TARIFFS

During the last few years, electrical engineers have given much study to the development of tariffs for electric power which will benefit both consumer and producer and lead to an increased demand for their product. Dr. Hopkinson pointed out fifty years ago that a steady load could be generated much more cheaply than a variable load, although their total loads for a given time were the same. This follows because with a steady load you require less machines in reserve than you do when there are peaks in the load for which much reserve plant is required which is only used for a comparatively short time. The total annual costs of a supply station depend on the running costs and the overhead costs, the former usually being only about one eighth of the latter. Hence any saving in the capital costs of the reserve plant enables appreciable savings to be divided between producer and consumer and would probably attract new consumers. One way of securing a uniform load is by means of a 'time-of-day' tariff. The rate at which the meter registers could be controlled by a ripple current superimposed on the supply current. The ideal case of continuous variation would be difficult, but if the rate at which the meter registers was changed at the supply station two or three times a day, the consumers being notified of the times of these changes, most of them would naturally be careful to keep down their consumption during the times when the meter was registering a high charge. This would increase the 'diversity' of the load and make it more uniform, thus lowering the station cost.

At first sight, this seems unpractical and far-fetched, but as several European cities use a 'time-of-day' tariff the discussion of one of these methods given in a paper by D. J. Bolton of the Regent Street Polytechnic, to the Institution of Electrical Engineers, on May 10, entitled "Superimposed Control Applications with Special References to Tariffs and Load Levelling", is worth studying.

The following are the details of the tariff of a Paris company. Consumers are divided into groups according to the 'size' of their installation. The size is defined by the maximum power consumption and depends on the number of rooms. The charge is 2 kw per day for a one-room apartment, 3 kw. per day fo two to four rooms, 4 kw. for five to six rooms, et Consumers whose power demand is less or equal t this amount are supplied through a single dial mete and are charged at the following rate. If the fir 'block' of the amount is charged at 3*d*. a unit, th second block will be charged at 1½*d*. per unit, an the remainder at 0·54*d*. per unit. The size of th first block is dependent on the number of rooms, an the second block size is always half the first bloc size. Large consumers can have supplies on a two part tariff consisting of a small fixed charge to cove lighting consumption and a running charge varyin with the time of the day. The fixed charge depend on the number of rooms and ranges from 11*s*. to £2 year for a one to six room flat. In addition to thi fixed charge, all the energy passes through a specia meter having three registrations. These are put int operation at appropriate times of the day by mean of timed relays on a centralized control system.

A Paris company was started in 1924 at a special rate for off-peak consumption but was changed into the three-rate tariff system outlined above. This tariff is little used in the purely domestic field, but there is a definite and growing utilization of it in the commercial field for large-scale cooking, oven heating and thermal storage. There would probably soon be a growing demand for it for domestic purposes, if the cost of the special metering required were reduced. This Paris company's charges for the peak period are 2·5*d*. per unit. This period lasts from 3 until 6 p.m. during the winter months. For the 'day' period, which lasts from 7 until 11 a.m. and 2 until 3 p.m. in the winter months and from 2 until 6 p.m. in summer, the price is 1·3*d*. per unit, and for the night period and all other times it is 0·53*d*. per unit.

Mr. Bolton concludes that the function of a 'time-of-day' tariff in Great Britain, both in the commercial and domestic field, would be to develop new loads not yet reached. It should supplement rather than supplant existing methods of charge.

CIENCE NEWS A CENTURY AGO

ying the Keel of the *Great Britain*

On July 19, 1839, the keel of the *Great Britain* was d in a dock at Bristol. This marked the beginning the construction of by far the largest iron ship of time. Like the *Great Western*, she was built for Great Western Steamship Co., for work on the lantic. Her construction was due to the collaboran of Isambard Kingdom Brunel, Thomas Richard ppy, William Patterson and Captain Christopher xton, R.N. At first it was intended to build the p of wood, but the unusual size led to the adoption iron. The largest iron vessels afloat were only of out 700 tons, but when completed the *Great itain* had a displacement of 3,618 tons. She was 9 ft. long between perpendiculars, 50½ ft. wide and ½ ft. deep. Her flat keel was made of wrought iron tes ¾ in. thick and 20 in. wide, welded into lengths 50–60 ft. Her stern and stem frame were both ought iron forgings. The ship had five watertight lkheads. Before the ship was commenced, Claxton d Patterson made a careful study of iron for shipilding. They found that iron afforded greater rength, buoyancy and capacity, and that iron ams 2½ in. thick would have the strength of oden beams 2 ft. thick. The *Great Britain* was t only the largest iron ship, but the largest wrought n structure for any purpose.

-discovery of the Aurora Islands

The *Athenæum*, in its accounts of the papers read the Royal Geographical Society on June 24, 1839, cluded references to the voyages of the *Medina* d *Mary* belonging to Mr. Burrows of New York, no on a recent expedition had re-discovered the rora Islands, which lie half way between the lkland Islands and South Georgia. In its issue of ly 20, 1839, the journal said: "A letter from our nited States Correspondent gives us some parulars of this expedition which are romantic enough deserve to be recorded. It appears that some four ars since a neighbour and friend of Mr. Burrows, a pt. Johnson, after consulting with and communiting to him his views and intentions, sailed from ew York to the Antarctic Seas. Letters were ceived from Johnson when in a high latitude, and ill sailing south, since which no information has en received either from or of him. These circumances weighed upon the mind of Burrows, who inking there was a possibility of rescuing his iend, resolved to follow the example of Capt. Back, d to proceed in search of him. Two small vessels ere accordingly fitted out for the expedition. The ccess in the principal object has been small, though the hazards run were great and the labour ost oppressive." When beyond the Falklands icergs were met with. "Subsequently Mr. Burrows, hen exploring in his boat, was wrecked on an eberg, but he was rescued by another boat driven y accident to the spot, where for three days he and is crew had been without food. For six months he ersevered, but without discovering any positive idence of the fate of his friend. He found, indeed, ear traces of eight different wrecks, a house conructed from the wrecked vessels and fitted up as a inter residence; several graves were near it, and ne body not interred. What a history 'in little' is ere in this last fact."

A Uranian Society

In July 1839, a preliminary meeting was held in the Meteorological Society's rooms, Bartlett's Buildings, Holborn, for the purpose of founding a society for the advancement of astronomical science. The society was to be called "The Uranian Society". According to the *Mechanic and Chemist*, Mr. W. H. White, F.R.S., the senior secretary of the Astronomical Society, presided at the meeting. Various resolutions were passed relating to membership, subscriptions, committee and officers, and it was agreed "that the anniversary of this society be held on the 22nd of March, that being the birthday of the immortal Laplace".

Sepulchral Urn

The *Gentleman's Magazine* for July 1839 contains the following information: "A curious discovery has recently been made on the ridge of hill which divides the Vale of Ovoca from the Vale of Redcross near Kilbride, County of Wicklow. The ridge of the hill affords many remains of remote antiquity, some are blocks of stone 15 ft. in length, laid parallel to each other, resembling burying places made for men of gigantic stature. A farmer was raising stones in a wild and solitary part of the mountains to fill up gaps; about two feet below the surface he turned up a flag, under which was a stone coffin, containing an urn in an inverted position, under which were two small bones laid parallel to each other. The coffin, consisting of six flags, was eighteen inches long, the sides were seven inches high, and ten broad, put together with neatness, the corners rectangular and the sides perpendicular; the inside perfectly clean and free from dust or mould. The urn was four inches deep, swelling in the middle, and contracting at both ends."

UNIVERSITY EVENTS

ABERDEEN.—At the graduation ceremony held on July 6, the honorary degree of LL.D. was conferred on Prof. C. L. Burt, professor of psychology in the University of London, and on Prof. A. Low, professor of anatomy in the University of Aberdeen from 1925 until 1938.

The degree of D.Sc. was conferred on Dr. J. Farquharson, for a thesis entitled "Magnetism and Polymerisation"; L. C. Snook, for a thesis entitled "The Effect of Diet on Ketonemia and Pregnancy Disease in Breeding Ewes"; and on H. Waring, for a thesis entitled "The Relation of the Pituitary Gland to the Chromatic Function of Fishes" (*in absentia*).

ST. ANDREWS.—The degree of M.A. *ad eundem gradum* has been conferred on Dr. E. Finlay Freundlich, Napier lecturer in astronomy. The degree of D.Sc. has been awarded to Dr. J. D. Robertson for a thesis entitled "The Nature and Movements of Interstitial Fluids and Aqueous Humour".

Dr. F. L. Arnot, whose work on ionization in gases has been approved for the degree of Sc.D. by the University of Cambridge, has resigned his post as lecturer in natural philosophy in the United College, having been appointed to a lectureship in his old University of Sydney, New South Wales.

APPOINTMENTS VACANT

Applications are invited for the following appointments, on or before the dates mentioned:

Graduate Lecturer in Engineering at Lincoln Technical College—Director of Education, City Education Office, Lindum Road, Lincoln (July 19).

Lecturer in Chemistry (Organic) at King's College, Newcastle-upon-Tyne—Registrar (July 19).

Teacher of Mining Subjects at Leigh Municipal College—Director of Education, Education Department, Town Hall, Leigh, Lancs (July 20).

Dietitian at the Middlesex Hospital, W.1—Secretary-Superintendent (July 22).

Assistant Technical Advisers in the Engineering Branch of the Air Raid Precautions Department—Establishment Officer, Home Office, Whitehall, S.W.1 (quoting Technical Adviser) (July 22).

Lecturer in Mechanical Engineering—Secretary, Robert Gordon's Technical College, Aberdeen (July 22).

Assistant III (Engineer) at the Fuel Research Station, East Greenwich—Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (quoting J. 29/9) (July 24)

Head of the Chemistry Department in the Municipal Technical College, Bolton—Director of Education, Education Offices, Nelson Square, Bolton (July 24).

Assistant Lecturer in Electrical Engineering at York Technical Institute—Secretary for Education, Education Offices, York (July 24).

Two Assistant Marketing Officers—Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (July 24).

Lecturer in Physiology—Secretary, King's College, Strand, W.C.2 (July 25).

Assistant Master to teach Physics—Headmaster, Royal Naval College, Dartmouth (July 25).

Lecturer in Metallurgy and Chemistry in the Technical College, Coventry—Director of Education, Council House, Coventry (July 26).

Chemists and Assistants III in the Royal Ordnance Factories—Under-Secretary of State (C 5), War Office, S.W.1 (quoting Appts. 156) (July 27).

Cartographers (Unestablished) in the Hydrographic Department of the Admiralty—Secretary, Civil Service Commission, Burlington Gardens, W.1 (July 27).

Lecturer in Engineering at the Cape Technical College, Cape Town—J. A. Ewing and Co. (London), Ltd., 73–74 Chiswell Street, E.C.1 (July 28).

Public Analyst and Government Bacteriologist in the Isle of Man—Government Secretary, Government Office, Isle of Man (August 1).

Temporary Assistants Grade III (Male) in the Meteorological Office—Under-Secretary of State, S.2.B. (Met.), Air Ministry, Adastral House, Kingsway, W.C.2 (August 14).

Principal Agricultural Officer in the Federated Shan States, Burma—High Commissioner for India, General Department, India House, Aldwych, W.C.2 (quoting Appointment 5/153B) (August 14).

Assistant Lecturer in Engineering—Registrar, University, Manchester 13 (August 14).

Lecturer in Natural Philosophy in the United College, St. Andrews—Secretary, University, St. Andrews (August 15).

Senior Lecturer in Bantu Studies at Rhodes University College, Grahamstown—Secretary, Office of the High Commissioner for South Africa, Trafalgar Square, W.C.2 (August 17).

Assistant Mistress to teach Physics—Principal, Ladies' College, Cheltenham.

Assistant Engineer for the Drainage and Irrigation Department, Malaya—Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/5765).

Mechanical and Automobile Engineers in the Royal Army Ordnance Corps—Under-Secretary of State (A.G. 9), War Office, S.W.1.

Technical Officers and Assistants II and III at various Royal Air Force Stations—Under-Secretary of State, Air Ministry (S 2. A/B. 8019), Berkeley Square House, Berkeley Square, W 1.

Civilian Education Officers, Grade III, in the Royal Air Force Educational Service—Under-Secretary of State, Air Ministry (E.S.1) (E. and M.), Adastral House, Kingsway, W.C 2.

SCHOOL BIOLOGY AND CITIZENSHIP

IN Great Britain and in other countries the present century, and particularly the last twenty years, have seen great efforts made to improve the school curriculum. It is true that these efforts have been largely experimental, and it cannot be said that they have produced that balanced course which would meet with general, even if not universal, approval. That is partly due to the difficulty of viewing with detachment the traditional courses through which we ourselves have passed, and partly to the endeavour to create new courses by interpolation of new subjects without due regard to the unity of the educational scheme as a whole.

Yet behind these efforts there are apparent ideals which in the end may greatly modify education in schools of all degrees. One affects the pupil as an individual, for the clear trend of modern education is to lay more stress upon the personality, which must be developed through its own response and through the encouragement of initiative. The biological truth that it is not so much the impression from without, but the response of the organism from within which counts in development, appears to be a sound foundation for educational method.

The second ideal has been forced to the front by the antagonisms which have become so insistent within the nations themselves, and it affects the pupil not as an individual but as a member of society. It asks for knowledgeable citizens, able to see and think for themselves, to balance opposing points of view and to make their own decisions, self-confident enough in their own judgment to be independent. It implies that the schools must plan their courses deliberately to contribute to the foundation of sound citizenship.

These thoughts were evidently in the minds of speakers taking part in the educational discussions which had a prominent place in the Ninth Imperial Social Hygiene Congress held in London last week. There the emphasis was laid upon the subject of biology, and while this is but one of the arts and sciences which must contribute to the development of youth, it embraces interests and methods which offer advantages of their own. Particularly it presents an easy and natural gradient to human affairs, from the discussion of the common properties of all living things and their inter-relations to the dependence of man upon common plants and animals, and so to his general relation to his environment. But part of the environment of man is man himself, and so a logical scheme of biological studies must in the end include not only aspects of human physiology but also a wider human biology, objective studies of human populations, human relationships, racial significances or perhaps insignificances, and the like.

A new and forcible argument for the universal teaching of biology in schools was advanced by Prof. James Ritchie in an address upon the "Supply and Training of Teachers in Biology". Sir Richard Gregory and others have in the pages of NATURE and elsewhere directed attention to the difficulties which have arisen between the nations because of the inordinate progress of scientific knowledge and invention in recent years, and the failure of mankind to assimilate these advances and weld them into a social and moral unity. Prof. Ritchie suggested that the failure is partly due to the exclusiveness of science, and that the remedy lies in the creation of a national appreciation of the social and moral implications of scientific knowledge. So soon as biological knowledge, and that embraces knowledge of human relations, becomes a common heritage of every child in the country, the nation would be conditioned for that blending of knowledge and moral sense which has lagged behind in this age of scientific progress.

If that prognosis be accurate, the introduction of biological teaching into all schools, under graded schemes covering the school life of a pupil, becomes a matter of national importance. Distinct progress has been made in Great Britain since the Zoology Organization Committee of the British Association reported in 1921 that "it is a common fact that in England alone, among civilized countries, a boy and girl can reach the age of 18 or 19 years and leave school without having received any school instruction in animal physiology or the natural history of animals". At that time, many lands abroad had already established graded courses in biology which were shared in, not by a few scholars passing on to a specialized course in science in the universities, but by all pupils without exception. Some of the lee-way has been made up in Great Britain, particularly in England and Wales, though Scotland still seems to lag behind; but much has to be done before biology can be looked upon as a school subject universally adopted.

Yet if the subject holds in its interests and content the values that have been claimed for it, its introduction and prosecution in the proper spirit in schools is a matter of national import, which may have beneficial repercussions towards the amelioration of social relations within the nation and between nations. Several speakers in the course of the discussions at the Social Hy Congress pointed out that upon the univer lies a heavy responsibility in this respect, they undertake the training of the majority men and women who as teachers are to b the disseminators of biological knowledge thr out the nation; and it was suggested that, a few exceptions, they have failed to live their responsibilities. University courses, pa larly in zoology, are not adapted to giv student who is to become a teacher that co with animals in their relations to environ and to each other which must form a ground in school teaching.

Furthermore, the universities have u sciously done an ill-turn to the service of bi as a national asset by favouring research a expense of school teaching; the best me usually guided into the paths of scientific in gation, and second raters are often looked up good enough for the services of scientific educ and the investigations it so badly needs. there is any situation that requires re-examin in the nations to-day, it is the chasm bet scientific progress and the knowledge and spi use that progress solely for the benefit of man No certain method of bridging this gap is evi But any reasonable suggestion is worthy of and if, as has been suggested, the national tea of biology is likely to create a scientific attitu mind such that appreciation of the social moral implications of science becomes s nature, then the best men and women are no good for a task upon which may depend ultimate progress of humanity.

ANALYTICAL ASTROPHYSICS

An Introduction to the Study of Stellar Structure

By S. Chandrasekhar. (Astrophysical Monographs sponsored by *The Astrophysical Journal.*) Pp. ix+509. (Chicago: University of Chicago Press; London: Cambridge University Press, 1939.) 50*s*. net.

EDDINGTON'S "Internal Constitution of the Stars" was published in 1926 and gives what now ranks as a classical account of his own researches and of the general state of the theory at that time. Since then, a tremendous am of work has appeared. Much of it has to do the construction of stellar models with diff equations of state applying in different Other parts deal with the effects of va chemical composition, with pulsation and tida rotational distortion of stars, and with the p relations between the interior and the atmos of a star. The striking feature of all this w that so much can be done without assuming particular mechanism of stellar energy-gener Only such very comprehensive assumption ade about the distribution and behaviour of the nergy sources that we may expect future knowdge of their mechanism to lead mainly to ore detailed results within the framework of the xisting general theory.

The work does actually appear at the present ime to be entering upon the new phase in which nown physical laws of energy generation will be mployed. For nearly ten years, it has been enerally believed that the main source of stellar nergy is nuclear transmutation. But only in the ast year or two have sufficient laboratory data n nuclear reactions accumulated to facilitate he quantitative study of its mode of operation; nd only this year has Bethe been able to give the first general survey of the possibilities which is fairly free from hypothetical steps. Incidentally, it is also likely that the theoretical etails of the absorption of radiation in stars soon acquire a more trustworthy physical basis.

The time is therefore opportune for the publication of an authoritative survey of the general theory of stellar structure. Indeed, there seems to be a demand for two rather different expositions, designed for readers with different requirements. Astrophysicists in general would doubtless welcome, before the subject fully enters its new phase, an expert summary of the main results achieved since the appearance of the "Internal Constitution of the Stars". This is not the book which has been written by Dr. Chandrasekhar. But such a book would apparently be more in keeping with the avowed aims of the present series of monographs, and one hopes that the editors may yet supply this need. On the other hand, the developments which we anticipate during the next few years will almost certainly engage the attention of research workers whose training has been in pure physics. They will require an accessible and authoritative account of the astrophysical setting of their work, and they will find their need to a very great extent met by Dr. Chandrasekhar's book.

The scope of this book is deliberately restricted to the most fundamental aspects of the theory. It constitutes in fact a courageous attempt to reduce a branch of astrophysics to analytical or 'rational' form after the manner of classical mathematical physics. The spirit which inspires it is revealed in the author's remark that "the logical rigor and beauty of Carathéodory's theory [of thermodynamics] may be regarded as an example of the standard of perfection which should be demanded eventually of any physical theory, including the theory of stellar structure". So it is not surprising to find the first 'astrophysical' chapter headed "Integral Theorems on the Equilibrium of a Star" and giving a series of elegant inequalities involving the central and mean values of the temperature, pressure, and density in stellar configurations about which the fewest possible assumptions are made. The next astrophysical chapter is on gaseous stars and may roughly be described as an up-to-date version of the theory initiated by Eddington. This is followed by a full account of the bearing of the chemical composition of stars on the general theory, discovered by Eddington and Strömgren, and of its application by the latter to the interpretation of the Hertzsprung-Russell diagram, and describes methods which are certain to play an essential part in future developments. The next chapter regards the subject from a fresh point of view; the outer envelope of a star may be studied under simplified assumptions, and Dr. Chandrasekhar shows how this study leads to significant conclusions about the central condensation of stars and also yields partially independent checks on the preceding work. Subsequent chapters deal with theoretical stellar models in which various general assumptions are made concerning energy generation, or in which the matter may be wholly or partially degenerate, and describe the application of the latter to the theory of white dwarf stars. The closing chapter forms an introduction to the theory of energy generation by nuclear transmutation, in which no attempt is made to maintain the rigorous treatment hitherto employed. Many of the methods and results in these chapters are new, as are many of the extremely useful tables which give both astrophysical results and auxiliary computational material.

These chapters occupy, however, barely half the book. Others are devoted to physical principles, general thermodynamics, radiation theory, and quantum statistics. While each is a masterly account of the topic reviewed, it is probably true that the bulk of the material contained in them is nowadays part of the general equipment of the type of reader most likely to benefit by the rest of the book. There is also a chapter of a hundred pages on "Polytropic and Isothermal Gas Spheres" which is effectively a pure mathematical tract on Emden's differential equation, and might preferably have appeared separately in that form.

The material is throughout presented with enviable crispness and clarity of expression. The work will undoubtedly become an indispensable handbook for future researchers in this field. Nevertheless, one is compelled to think that they would find its size, and incidentally its price, more acceptable had the non-astrophysical portions been drastically reduced.

W. H. McCrea.

THE FUNCTION OF EDUCATION IN DEMOCRACY

Educating for Democracy
Planned and edited by J. I. Cohen and R. M. W. Travers. Pp. xxx+458. (London: Macmillan and Co., Ltd., 1939.) 10s. 6d. net.

THE challenge to democracy at the present time derives part of its strength from the way in which education has been made to serve the purposes of the Fascist State. Those who believe in democracy have, however, been slow to realize that education for democracy is something quite different from education for Fascism, though an admirable pamphlet on "Bias in Education" issued last year by the Association for Education in Citizenship indicates that the danger of the tendency for education to become little more than a means of adjusting the individual to certain restraints on his or her liberty is already realized in some quarters. The present book is an admirable attempt to state the function of education in English democracy, and the participation of twenty-three authors has in no way prevented the presentation of a consistent and convincing exposition of the possibilities of deliberately planning our educational system to serve the purposes of democracy on a factual rather than a political basis.

The several essays vary considerably in scale and scope. Together they give a very comprehensive picture of the possibilities and they are characterized by a remarkable unity of thought. Scientific workers will welcome the expression given to the importance of bringing our education into vital relations with the deeper and more significant movements in our national life, of which probably the most significant is the modern transformation of industry under the influe science. Sir Percy Nunn emphasizes the i ance of the general outlook of the school a spirit which dominates its activities, and of greater stress to-day on the intrinsic va man's creative powers. It should be an es function of the school to awaken and devel special gifts and talents which in time will the community with their fruits.

A dominant theme in this symposium necessity of considering the school as an or the community and not a self-contained Scientific workers will find in the volume nc a lucid statement of the functions and contri of education from the nursery school to tl versity, but also stimulating and suggestive ments on important problems such as the fur of the universities and of the technical oc freedom of teaching and limitation of entry universities, recruitment for the professior elimination of bias in adult education, the of science in modern education, the significa the social sciences, the opportunities in ind psychology and vocational guidance and sel Sir Philip Hartog contributes a discussion place of examinations in the social syster Prof. K. Mannheim an analysis of the socio approach to education and the function of analysis in helping the individual to ma adjustments.

Few will put down this book without convinced that democracy can only f meet the challenge of Fascism to-day n inherent weakness but by sheer neglect possibilities that lie in its hand.

R

BEDFORD COLLEGE, LONDON

A History of Bedford College for Women, 1849-1937
By Dr. Margaret J. Tuke. Pp. xvi+364+12 plates. (London, New York and Toronto: Oxford University Press, 1939.) 10s. 6d. net.

THERE were several reasons why the history of Bedford College should be written, and every reason why Dame Margaret Tuke, who took the chief responsibility for guiding its destinies during a period of twenty-three years, should have written it. Her story necessarily includes a great deal of detail which is meant for the information of past and present members of the College with an admirable sense of proportion, sh the story so as to bring out, not only th which the College has played in the advan of the higher education of women, but al striking and often amusing changes in the background and setting of the College, duri long stretch of years since 1849, the date foundation.

Opened in that year at a house in B Square, London, the College was at first reall other than a school for young ladies of the pla period. Gradually it began to assume som ore nearly approaching the status of a college, d in 1874 moved to more suitable and dignified emises in York Place, Portman Square. Four ars later, the University of London, then an amining body, threw open its doors to women ndidates, and Bedford College, as it was and is ill called, naturally availed itself of the opporunity thus provided. Good work continued to done in adverse circumstances, the buildings ing crowded and ill-adapted for their purpose. here were, we are told, no proper lecture theatres, ere was only an apology for a laboratory situated a basement, and adjoining a small gymnasium hich was the sole provision for physical exercise. here was not adequate room for meals, and the brary was rudimentary.

These details are worth recalling, because a omparison with the fine buildings occupied by he College in Regent's Park since 1913 suggests a ngularly apt illustration of the enormous strides ade by the cause of women's education; and edford College enjoys the distinction of having, o to speak, seen the whole thing through. It ecame a school of the University in 1900, and as granted a Royal Charter in 1907. Naturally, here had existed during the more strenuous period desire to become affiliated to one of the great nd long established colleges, especially as the expenses of adequate equipment for work on the science side would thus have been avoided or minimized. But the party which believed in a great and complete university institution, run by women for women, prevailed, with the results which we now see.

From the first, the services of men were sought and obtained for help which men can generally best give. In their time, for example, the names of F. W. Newman, Mark Pattison, Erasmus Darwin and Arthur Acland were associated with the College, which is under a lasting obligation to the last-mentioned for his work in setting the finances of the College in good order.

But having said so much for the men who have been associated with the College, we must end by saying that had it not been for certain outstanding women there could have been no Bedford College as we know it. Mrs. Reid, the founder and benefactor, "Eleanor Smith of Oxford" (sister of H. J. Smith, the distinguished mathematician), Miss E. Penrose, the lady on whom the title of principal of the College was first conferred, Miss Hurlbatt who succeeded her and carried on until the appointment, in 1906, of Miss Tuke, in whose time the mighty changes indicated above have mostly taken place—these are the persons who really made Bedford College what it is.

NEURO-PHYSIOLOGY

Physiology of the Nervous System
By Prof. J. F. Fulton. (Oxford Medical Publications.) Pp. xv + 675. (London, New York and Toronto: Oxford University Press, 1938.) 25*s*. net.

IN recent years, considerable attention has been paid to neuro-physiology, and marked advances have taken place in our knowledge of the subject. As so few monographs have been available, Prof. J. F. Fulton's book "Physiology of the Nervous System", which he describes as an exposition of the experimental approach to the subject, is of special interest.

In this monograph, Prof. Fulton has emphasized two concepts. The first is the evolutionary principle of levels of function which implies that headward segments of the brain have become dominant over caudal, and that when higher parts are removed many activities of lower segments are, after a time, released. The second relates to the extensive interaction normally occurring between somatic and autonomic reflexes.

The historical notes which are placed at the head of each chapter are of interest, and the author may be congratulated on the manner in which he has drawn the threads together. In some instances, the account demonstrates how the subject came to be developed. For example, it is pointed out in reference to postural reflexes that "Sherrington had been using the decerebrate preparation to study individual reflexes and the underlying mechanism of reflex transmission within the nervous system. After Magnus had left Liverpool, Sherrington and Magnus independently noted the effects of rotation of the head on the posture of a decerebrate cat. When Sherrington learned that Magnus had seen the reaction, he urged him to pursue it and stated that the observation would be his to elucidate." That Magnus carried out these observations with great success is now a matter of history.

Prof. Fulton has succeeded in giving an admirable account of the functions of the central nervous system in relation to somatic reflexes. It is regrettable, however, that the author has not been able to pause and give more attention to the question of chemical transmission of the nerve impulse at the synapse. It must be pointed out that those originally responsible for the hypothesis have never applied it to the central nervous system. The experiments which are quoted as conclusive evidence against chemical transmission in the sympathetic ganglion, namely, that the liberation of acetylcholine has no relation to discharge of impulses, have been repeated since the publication of this book, and have not been confirmed.

It is scarcely possible, in view of the evidence in support of chemical transmission in the ganglion, to dismiss the hypothesis with the statement "that the humoral concept of central transmission has served its purpose". It may be recalled that only a few years ago the postulates of Keith Lucas, which are now stated to harmonize in a striking manner with the new concept, were also supposed to have served their purpose.

The treatment of the autonomic nervous system is open to criticism. Important investigations have been omitted and the chapter as a whole lacks balance and body. It is difficult to understand why Prof. Fulton has attempted a new definition of the autonomic nervous system. Langley's original definition of the autonomic system, "The nerve cells and nerve fibres, by means of which efferent impulses pass to tissues other than mult nuclear striated muscle", was clear and sati factory. It should be emphasized that refle responses involving involuntary tissues may elicited in response to stimulation of a somatic a visceral afferent nerve. Furthermore, somat reflexes may be obtained on stimulation of viscer afferent nerves. It is not necessary to extend th concept of the autonomic system to include viscer afferent fibres.

An excellent account is given of the recent wor on the cortex, and Prof. Fulton is undoubtedl right in emphasizing "the co-existence of autonom and of somatic representation which makes possib simultaneous and appropriate adjustments in th outflow of both autonomic and somatic systems"

There is no doubt that Prof. Fulton ha succeeded in carrying out a difficult task wit distinction. He has given an excellent summar of the experimental investigations carried out i recent years, and his book will undoubtedl stimulate further work. The bibliography is remarkable achievement: it includes 136 references to anatomical and physiological paper This section of the book will be of great value t senior students and research workers. The mono graph is an important contribution to the subject

NITROGEN FIXATION AND NUTRITION

Cattle Fodder and Human Nutrition

With Special Reference to Biological Nitrogen Fixation. By Prof. Artturi I. Virtanen. Pp. vi+108+8 plates. (Cambridge: At the University Press, 1938.) 7*s.* 6*d.* net.

THE process of nitrogen fixation is at once one of the most intriguing and elusive of the unsolved problems of microbiology. It is apparently brought about only by the living cells of certain bacteria and algæ, and the immediate products of nitrogen fixation are in consequence mixed with those of protein degradation whose presence is inevitable in an active cell. This fact has made it very difficult to determine which nitrogen compounds, found in the cells or in their surroundings, are to be regarded as the early products of fixation.

The important contributions that Prof. Virtanen has made to the theory of nitrogen fixation arose from his discovery that the nodules of certain legumes often secrete combined nitrogen into the root surroundings, and that this nitrogen is almost all in the form of *l*-aspartic acid and to a smaller extent of β-alanine. He argues that the products of protein degradation should consist of a variety of amino-acids and consequently cannot accoun for the aspartic acid, which he claims is a primary product of nitrogen fixation. It may be said here that, while this contention is very reasonable, i has not been proved that the products of fixatio have remained unaltered in passing from the bacteria, through the nodule tissue, to the exterior. Prof. Virtanen supposes the bacteria to produce hydroxylamine, which is not detected since it reacts at once with oxalacetic acid (found in pea sap) to form an oxime which is then reduced to aspartic acid. In support of his theory, Virtanen has been able to obtain a fixation of nitrogen by crushed nodules supplied with oxalacetic acid. But we are still in complete ignorance as to how the nitrogen is caused to combine, or as to whether hydroxylamine is in fact the first-formed product.

The nature of the process by which nitrogen compounds are secreted from legume nodules is in itself a remarkably interesting problem. Prof. Virtanen seems to have established the existence of such a process and of the uptake of the secreted compounds by other plants if grown in association with a legume. But attempts to confirm his results have sometimes succeeded and sometimes not, and

feels that there are factors controlling the
retion process that have not yet been detected.
he book under review comprises four lectures
en in England during the autumn of 1937. In
first two of these the author gives an excellent
l very clear exposition of his experiments on
secretion of nitrogen compounds by legumes
l of his resulting theory of nitrogen fixation.
third lecture deals with the supposed lack of
amins in the diet of the Finns. The conclusions
be drawn from the analyses quoted depend on
minimal requirements of average human
ngs for each vitamin, a point concerning which authorities are not well agreed. The fourth lecture describes the now well-known A.I.V. process of ensilage, which was developed by the author, who urges that with its help, protein-rich legume fodder can be preserved with its content of vitamins for winter feed, thus improving the vitamin content of winter milk, to the great benefit of the populace.

The book concludes with a general survey in which the reader is very nearly convinced that the work on investigating nodule secretions on one hand, and the development of the A.I.V. silage process on the other, formed in themselves an example of "associated growth". H. G. T.

A STUDY OF DEWPONDS

wponds in Fable and Fact
Alfred J. Pugsley. Pp. x + 62 + 8 plates.
ndon: *Country Life*, Ltd., 1939.) 3*s*. 6*d*. net.

R. PUGSLEY describes his little book as
"mainly another nail in the coffin of an
eady dead idea". He goes on to say, however, that
e body won't lie down", which is true enough.
The originator of the belief that certain upland
nds are maintained in times of drought by
ect condensation from the atmosphere appears
have been Gilbert White of Selborne. Letter
XIX in "The Natural History of Selborne" sets
t the theory in detail. This simple and, at first
ht, attractive idea gained ready acceptance. It
been demolished scientifically on various
asions; but the writings of the demolishers
ve never enjoyed a publicity comparable with
writings of Gilbert White. Mr. Pugsley's book
ntains an adequate summary of the literature,
d like other competent investigators he has
ched the conclusion that the behaviour of the
called dewponds is accounted for by the
dinary agencies of rainfall and evaporation.
describing the 'dew' pond idea as "one of the
ggest pseudo-scientific swindles that has ever
en foisted on unthinking readers of popular
riodicals by writers who have not troubled to
amine the facts themselves", he can scarcely be
cused of over-emphasis.

The word 'dewpond' is, it appears, of relatively
ent origin, the earliest reference to the term
ing in a pamphlet by Rev. H. P. Slade published
1877. The title-page of Slade's pamphlet,
produced by Mr. Pugsley, might lead one to
ppose that it was a blatant and valueless exsition of the old dewpond hypothesis. It was,
the contrary, a very thorough study of the
ctors involved in the maintenance of a pond
the north-east Berkshire Downs, based on accurate observations of rainfall, water-level and consumption by animals. As Slade's work is now almost forgotten, it is of interest to recall that it was noticed and warmly praised by G. J. Symons in his "British Rainfall". Mr. Pugsley also pays tribute to the work of E. A. Martin, who seems to have been the first to demonstrate the fact that the surface temperature of the water in a so-called dewpond scarcely ever falls below the dew-point of the air above it.

Although, in face of the evidence summarized so clearly by the author, the traditional ideas about dewponds must be thrown overboard, there is no doubt at all that they served, and continue to serve, a most useful purpose in areas where surface water supplies are difficult to get. Their construction calls for great skill acquired by long experience, for it must be remembered that the materials naturally available in these areas do not readily lend themselves to durable water-tight construction, and the power to retain water indefinitely is the essence of the contract. It is a mistake to suppose, however, that there is anything secret or mysterious about the mode of construction. Mr. Pugsley details quite a number of methods. Another myth exploded in the book is that many of the ponds date from neolithic times. He points out that the cleaning process which must be carried out at fairly frequent intervals necessarily involves the removal of some of the puddled material from the bottom of the pond. He estimates, therefore, that such a pond would not last more than 100–150 years, unless entirely remade.

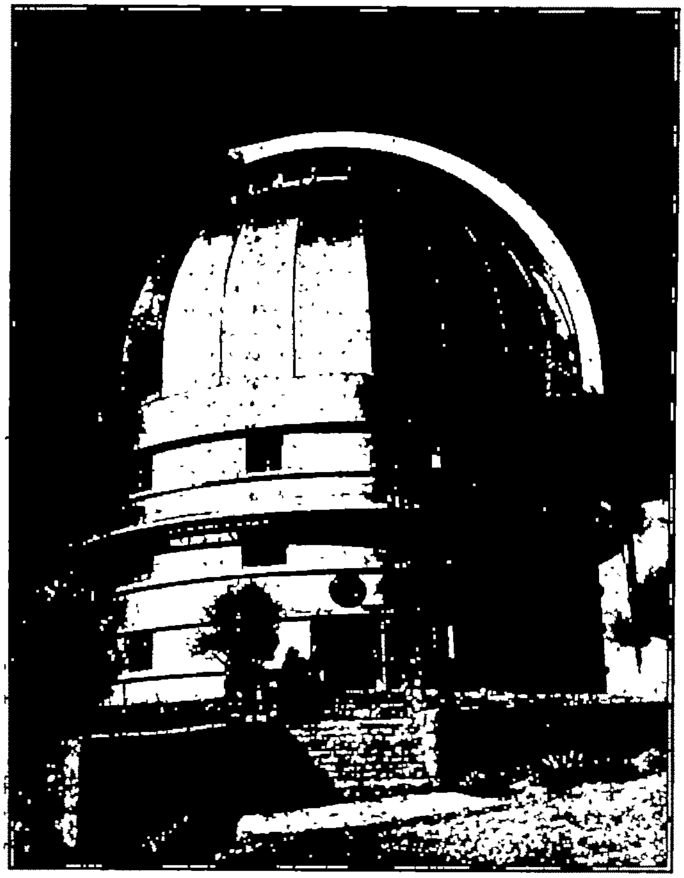
The book contains some pleasing photographs of typical dewponds and it may be cordially recommended to those who desire, at trifling cost to themselves, to have at hand a means of clarifying the ideas of their unscientific friends on the subject of dewponds. E. G. B.

THE McDONALD OBSERVATORY, FORT DAVIS

By Prof. Otto Struve

ON May 5, the president-elect of the University of Texas, Dr. H. P. Rainey, formally dedicated the McDonald Observatory and declared it open for research "as an enduring symbol of the insatiable desire of man to discover the secrets of the universe and as a symbol of the freedom of man's mind to explore the boundless areas of truth without any restrictions whatsoever".

The new observatory is located in the Davis Mountains of western Texas, at an altitude of 6,825 ft. above sea-level. The principal instrument is an 82-inch reflector completely designed and built by the Warner and Swasey Company of Cleveland, Ohio. The disk for the mirror—of Pyrex glass—was cast by the Corning Glass Works on December 31, 1933, and was ground and figured by Mr. C. A. R. Lundin, optical expert of the Warner and Swasey Company. Dr. J. S. Plaskett, director emeritus of the Dominion Astrophysical Observatory at Victoria, B.C., acted as scientific consultant for the Company and performed the laborious optical tests in the shop, before the mirror was installed in its cell on Mount Locke. The following is quoted from Dr. Plaskett's address given at the dedication:



[Photo by Paralto Studio, Austin, Texas.

McDonald Observatory at Fort Davis, Texas, on Mount Locke.

"The 82-inch mirror was thoroughly tested in the optical shop by measures of radius of curvatures of various zones. The resulting longitudinal aberrations at the focus were on the average only one thousandth of an inch and these, translated into deviations of the surface from tl
amount to seven ten millionth
thirtieth of a wave of visual li

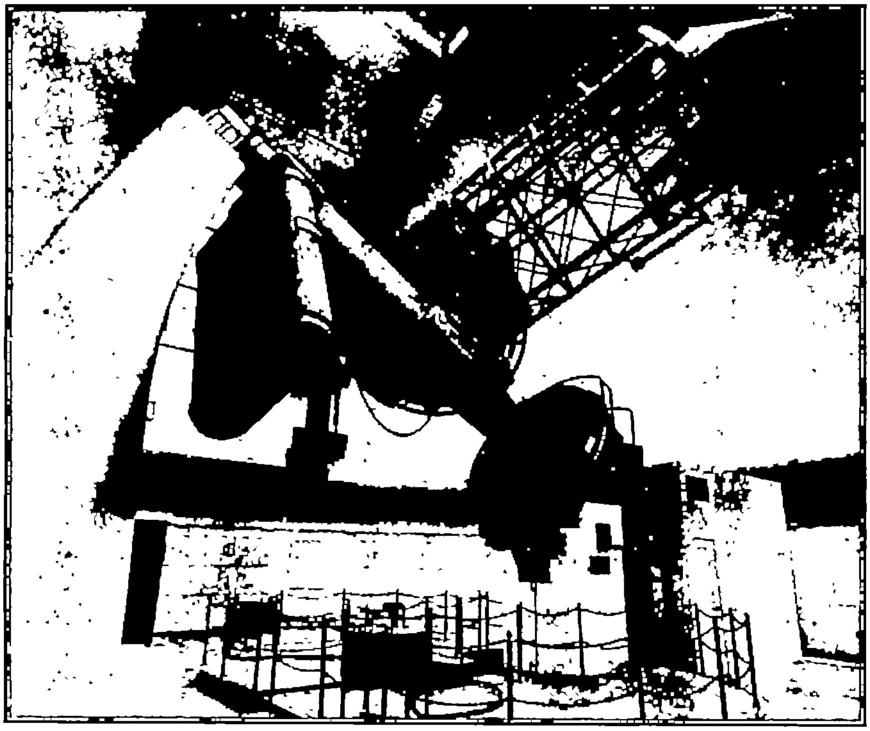
focal length of the Coudé arrangem

The Cassegrain focal length is 91 ft. (*f*/13). Three spectrographs are now in use. The dispersing nit of one consists of a pair of quartz prisms, made by Bausch and Lomb, four inches in aperure ; or of a pair of light flint-glass prisms made by William Gaertner of Chicago. The collimator is one metre in length. A camera lens of *UV* Jena glass, having a focal length of 500 mm., gives a inear dispersion of 50 A./mm. at 4000 A. with the quartz prisms, or of 25 A./mm. with the glass prisms. Three Schmidt cameras of *f*/2, *f*/1 and *f*/0·5 provide smaller dispersions. The limiting magnitude with the 50 A./mm. dispersion is about 9·5 ; that of the *f*/1 Schmidt camera is about 15.



THE 82-INCH REFLECTOR OF THE McDONALD OBSERVATORY.

Another spectrograph is equipped with a diffraction grating ruled by Prof. R. W. Wood (aluminium on glass) and with a grating ruled by Dean Henry G. Gale of the University of Chicago (speculum metal). Both gratings were excellent and concentrate a large amount of light in the first order on one side. We expect that the aluminium grating will be particularly useful in the infra-red, while the speculum metal grating, recently plated with gold, will be used in the green and near red regions of the spectrum. There are two camera lenses, one designed by Dr. G. W. Moffitt, the other by Prof. F. E. Ross. The linear dispersion of the shorter focus lens is 80 A./mm. This lens, as were several other spectrograph lenses at the McDonald Observatory, was made by J. W. Fecker of Pittsburgh, Pennsylvania.

A low-dispersion spectrograph is used at the Cassegrain focus interchangeably with a large direct camera and a filar micrometer for visual double-star work. This spectrograph is used principally for the determination of spectral types and luminosities of very faint stars.

There is no Newtonian arrangement, and the principal plate holder is in the prime focus itself. The guiding is done from the rim of the tube. The mechanical construction of this elaborate instrument is due to Dr. G. W. Moffitt and Prof. G. Van Biesbroeck.

The prime focus is also equipped with a slitless spectrograph of novel design, due principally to Mr. L. McCarthy. The field is approximately 40′ in diameter, and the limiting magnitude is 15 or 16. The dispersion is about 250 A./mm.

PROGRAMME OF WORK AND ORGANIZATION

The telescope has already produced valuable results. Dr. G. P. Kuiper has obtained numerous spectra of faint proper motion stars and has discovered several new white dwarfs and about two dozen stars of a class designated by him as subdwarfs. Dr. A. Unsoeld of Kiel and the present writer have obtained a large amount of valuable spectrographic material for the study of line-profiles and of equivalent widths in the ultra-violet region of the spectra of early-type stars. Dr. J. Greenstein and Dr. C. K. Seyfert have taken photographs in the prime focus for star counts and for the determination of the colours of condensations in large spirals. Dr. Elvey and the writer are collaborating in the determination of the spectroscopic orbit of the remarkable spectroscopic binary and eclipsing variable μ^1 Scorpii; the former will undertake the study of the line profiles of the principal helium lines broadened by an unusually large amount of rotation, while the latter will measure the radial velocities. Remarkable, but as yet unexplained, variations in the line profiles have been detected.

One of the most interesting features of the Observatory is its organization. The entire Observatory was built from a bequest of one million dollars left by Mr. W. J. McDonald, a banker of Paris, Texas, to the regents of the University of Texas, "for the purpose of aiding in erecting and equipping an astronomical observatory . . . for the study and promotion of the study of astronomical science". Under a 30-year contract, the McDonald Observatory will be operated jointly by the University of Texas and the University of Chicago, the Yerkes Observatory supplying the staff and the larger part of the operating expenses. The present writer combines the functions of the directors of both observatories. Dr. C. T. Elvey acts in the capacity of assistant to the director, and is in charge of the McDonald Observatory during the absence of the director. The permanent staff of the McDonald Observatory includes Dr. C. K. Seyfert, Dr. Daniel Popper and Mr. Walter Linke. The astronomers of the Yerkes Observatory rank as research associates and are given the privilege of using the reflector. The co-operative plan, now in force for seven years, has proved eminently satisfactory from all points of view. A considerable part of the original McDonald bequest has been saved and set aside for future development, or, in case the co-operative plan is dropped at the end of the present contract, for the independent operation of the Observatory by the University of Texas.

DEDICATION CEREMONIES

Through the generosity of the Warner and Swasey Company, a number of distinguished astronomers were invited as guests of the firm to attend the dedication and to take part in
day symposium on "Galactic and Extr
Structure". Prof. E. A. Milne came from
and spoke on "Cosmological Theories"
Bertil Lindblad, of Sweden, spoke on "Th
Interpretation of Spiral Structure" and

THE RECENT TREND OF RADIO DIRECTION-FINDING

THE radio direction-finder is an instrument for determining the direction of arrival of electric waves of the frequencies normally used in radio communication. Although it was introduced during the early years of the present century, it did not become a practically useful instrument until the valve-amplifying receiver was developed and provided the necessary sensitivity in the reception of radio signals. In its early form, the radio direction-finder, using closed loop aerials and operating on wave-lengths of from a few hundred to several thousand metres, was applied as an aid to marine navigation, and as a means of locating the position of unknown transmitting stations; in addition, however, the instrument provided a very useful tool in connexion with the study of the mode of propagation of electric waves.

Arising out of these applications, it was noticed that under certain conditions of wave propagation and beyond certain minimum distances of transmission, the directional indications of the instruments were subject to large and variable errors, which were found to be due to the action of the horizontal components of electric force in the arriving waves on the horizontal sides of the receiving loop. The remedy for this state of affairs was to be found in a British patent applied for by F. Adcock in 1918, in which it was proposed to replace the closed receiving loops by pairs of spaced vertical aerials, so connected together that the resultant action of any horizontal components of electric force could be reduced to a negligible amount. The practical utility of this invention was demonstrated in 1926, and soon afterwards the Adcock direction-finder became a commercial proposition for medium wave-lengths.

This advance had the effect of increasing the range of usefulness of ground receiving stations to several hundred miles, at which distances polarization errors ranging up to 45° or more with the loop aerial were reduced to less than one tenth of this amount with the spaced vertical aerial. Limitations of space have delayed the application of this improved direction-finding system on board ship, but the closed loop type used on medium wave-lengths has so far been found sufficiently accurate for the comparatively modest range requirements of marine navigation. Since about 1930, two factors have had a major effect upon the trend of radio direction-finding investigations and their application. In the first place, the growth of aerial transport has given rise to a demand for accurate radio bearings of aircraft at distances ranging up to several thousand instead of several hundred miles; and secondly, the general trend of radio communication to shorter and shorter wave-lengths has necessitated the extension of direction-finding technique in a corresponding manner. For the particular case of aerial navigation, various radio beacons have been developed by which a pilot may be guided to an aerodrome and enabled to land under conditions of poor visibility, but the scope of such aids is usually limited to comparatively short ranges, except in the case of long straight air routes, such as exist in the United States of America.

In order to provide a useful radio-bearing service to aircraft at ranges between 200 and 2,000 miles, it is necessary to resort to the use of short waves, so that the comparatively minute transmitter power available on the aircraft may produce sufficient field intensity at the ground receiving station. For this purpose, spaced aerial direction-finders have been developed to a high standard of performance for the wave-length band 10–100 metres. Such instruments are now available, with either a simple aerial receiver in which the bearing is determined by rotating a goniometer search coil to a zero or minimum signal position, or a dual receiver and cathode-ray tube indicator in which the bearing is read from a visual trace on the fluorescent screen.

A detailed theoretical and experimental study of the principles of design and construction of such short-wave direction-finders has led to the conclusion that their inherent instrumental accuracy should be of the order of 1°, with maximum error values of 2° or 3° under the most severe conditions of reception of horizontally polarized waves. When such direction-finders were used in practice, however, it was found that the observed bearings of transmitting stations in known positions were subject to errors much greater than this, sometimes ranging up to 10° or 20°. This raised the question as to whether the instrument was still defective due to some undetected fault, or whether the measurements indicated departures of the arriving waves from the great circle plane between transmitter and receiver.

To assist in the resolution of this question, resort was had to an alternative means of direction finding, which, although first described by T. L. Eckersley in 1921, has not been brought into use as a practical instrument until within the past few years. In this case, the reception takes place on a pair of identical vertical closed loops, spaced a fraction of a wave-length apart and symmetrically connected to the central receiver in such a manner that certain instrumental defects inherent in the use of open aerials can be eliminated. It is convenient to use a visual receiver of the cathode-ray tube type, and various tests have demonstrated that the inherent instrumental accuracy of such apparatus is somewhat higher than that previously attainable.

When used for taking bearings on short-wave transmitting stations, however, it was found that the accuracy was not materially better than that hitherto obtained. It is to be concluded, therefore, that on the short wave-lengths under consideration, a severe limit is set to the accuracy of radio direction finding under certain conditions by vagaries in the propagation of the electric waves employed. The direction-finding instruments indicate the actual direction of arrival of the waves to a high order of accuracy, but this is not necessarily the direction of the transmitter, but rather that of the point of reflection or scattering of the waves from the ionosphere. It is perhaps fortunate that it is possible to avoi bearings obtained under such cond increased knowledge and experience indicate in precisely what circumstanc to rely upon the radio bearings obtai while, the use of these short-wave finders is adding considerably to our k the mode of propagation of electric wa the ionosphere.

In the range of wave-lengths below direction finding is in the early stages ment, but instruments of the close spaced aerial types have already bee ascertaining the possibilities of the a lengths down to 3 metres. It seems within this wave-length band, some a likely to be found in ascertaining the radio sounding balloon transmitters at one hundred miles or so. In this spher much more research is needed on the of waves as well as on the design and of the direction-finding instruments.

R

BIOLOGY, THE SCHOOL AND SOCIETY*

BY T. H. HAWKINS

EDUCATION OFFICER, BRITISH SOCIAL HYGIENE COUNCIL

THE acceleration of scientific invention during the last generation has been such that it has now considerably outdistanced the ability of man to assimilate knowledge and to make it an essential part of his social and ethical relationships. This was the theme of the address given before the Ninth Imperial Social Hygiene Congress by Prof. J. Ritchie, of the University of Edinburgh, who suggested that the failure is in some measure due to the exclusiveness of science, and that its remedy partly lies in the creation of a world-wide appreciation of the social and moral implications of scientific knowledge. That this appreciation can in part be brought about by biological knowledge was the keynote of the educational sessions of the Congress, which was attended by delegates from all parts of the Empire.

At the opening session, the speakers concerned themselves with the teaching of biology as a factor in health and character training. Mr. C. R. E. Gillett, University of Reading, in comparing the older public and newer State schools, suggested that the latter are now attempting to turn out a product which hitherto has presumably belonged exclusively to the former, namely, qualified to play his part in our chang democratic government. This citize keenly aware of his responsibilities t munity and would be imbued with suc social duty that he would readily und tasks which contribute to the welfare lishment of communal life. But whet to serve has demonstrably expressed matter of great doubt, and here onl would make it effective. The part t can play in health and character fo only become apparent if the pupil be keenly aware of the value of his train co-operation will be needed between physical training, domestic science, a and this should be unified by a 'p tude towards health on the part o staff as a whole. The part of the biolo in this co-ordinated form of health educ be that of the true scientific investiga with the children to elucidate rea rather than being a mere imparter information. If children were allo operate fully in the elucidation of sim biological problems, they would not fa

itical and inquiring attitude to their own health
blems, one which is active and forward and
a mere morbid dwelling on bodily ills.

n considering character formation, it is well to
ne the main objectives of biological teaching;
, the acquisition of information; secondly, the
elopment of methods of thinking; thirdly, the
uction and application of principles; and
rthly, the formation of attitudes. The forma-
n of desirable attitudes can be fostered by
ctive science teaching based on direct personal
eriences. The problem of sex education is
nplex and difficult, but at least the biology of
can be treated objectively by the teacher as a
blem which is as vital as any other. Whether
teacher is able to deal with the ethical, moral
l emotional aspects of sex will depend largely
his own personality and character. The recogni-
n that most of the problems besetting the world
fundamentally biological might lead people to
k for biological solutions. Ecology and heredity
ld be used to discuss the inter-relationships of life
l the effects of selective breeding, while, in common
th other sciences, laboratory methods could be
ed to distinguish between speculation and opinion.

Dr. F. C. Kelly, director of the Iodine Educa-
nal Bureau, dealt with the efforts that are
ing made to reduce the gap between those who
e engaged in ascertaining the theoretical facts
nutrition and those whose duty is the applica-
on of that knowledge to the practical affairs of
ublic health. Co-operation between educationists,
edical men and agriculturists might be consider-
ly extended. While the vital problem of mal-
trition and sub-standard health is fundamentally
ne of food production, yet education also has an
sential place. The application of education
hould be extended in two directions. The newer
nowledge of nutrition and its principles must
rst be made known to those who are in a position
influence others, such as Government officials,
ealth, agriculture and education officers, em-
loyers of labour, missionaries and other welfare
orkers. But there is also the great problem of
ducating those whose nutrition it is desired to
nprove. Besides teaching the right use of food
relation to such aspects as cooking, storage and
reservation, there is urgent need for educational
easures to overcome innate conservation, pre-
udice, religious scruples and food taboos. The
eaching of biology in schools might help to over-
ome these prejudices by reaching towards the
ssential unity of Nature, and, in checking the
ontinually increasing pace of analytical inquiry,
ffect a harmonious synthesis of all the complex
nowledge now at our disposal.

Prof. H. D. Kay, University of Reading, suggested that the gaps in the teaching of nutritional science will only be filled when two conditions have been satisfied. One is the need for the training of a sufficient number of teachers capable of dealing with agricultural and rural biology to enable *all* senior and secondary school children in country districts and small towns to receive adequate elementary instruction in environmental science. The other is the need for the training of a sufficient number of teachers having a sound up-to-date knowledge of the elements of nutritional science to enable *all* pupils in senior and secondary schools, in town and country alike, to receive adequate instruction in this field. That the former condition merits immediate attention is borne out by the fact that less than ten per cent of the future farmers of Great Britain attend agricultural colleges or farm institutes, whereas practically all now pass through senior or secondary schools.

An educationist, Mr. W. L. Sumner, of University College, Nottingham, went on to explain the function of the school in creating an ideal of health as an attainable goal. Whilst no detailed physiological knowledge is required, on the other hand a smattering of the old formal botany and zoology would not suffice, a statement which was expanded by Prof. L. P. W. Renouf, University of Cork, and Mr. J. H. Lloyd, University of Wales. Throughout all science courses, the human and everyday value of science should be stressed. Food and feeding and problems connected therewith might find their way into other school studies. Arithmetic might deal with food prices and food values, lists of ingredients, comparison of consumption, etc. The pages of history and geography are full of stories of diet which could be used to good advantage. A knowledge of elementary dietetic principles would enable the public to distinguish between what is true and what is misleading in the advertising of foodstuffs. This knowledge would have far-reaching effects on the health of the nation; during the last twenty years amazing changes have taken place, but the problem of better food for all has still to be resolutely tackled. The psychological and æsthetic aspects of food and feeding are further considerations to which the teacher might give his attention. The presentation of food in attractive form and in pleasant surroundings is a matter in which English people might gain much from Continental methods. Although it would be inadvisable to attempt to copy directly these methods, their study might lead to the introduction of an eclectic spirit.

With these considerations in mind, the Congress turned to discuss the equipment of the ordinary teacher in biology. Although the development of biology in schools during the last ten years has been really remarkable, Prof. Ritchie pointed out that Great Britain still lags far behind nearly every other country in the world, and school courses are often ill-adapted for their purpose in education. Now that the educationist has realized that the pupil is no empty sarcophagus into which the mummy called 'information' should be stuffed, then the objective of making use of the child's own initiative and response might be achieved. As in the world of living things, the educationist is realizing that it is the response from within and not the impression from without which counts. Another conception which is helping to direct the flow of educational practice has arisen from the difficulties and disturbances which have upset the peaceful course of national life in recent years. By inducing independence of thought and balance of mind, school education should lay the foundations of mental stability and of the appreciation of the significance of social relationships which would prepare the child for the responsibilities of citizenship.

The fundamental interest of children in Nature opens up easy ways of inducing response and initiative. To be effective, biology teaching should run in graded stages throughout the whole school period, as indeed it does in many countries. Further, it should place the pupil in contact with living things, in school and out of school, as a basis for the understanding of the activities and relationships of life. Finally, it should in its later stages boldly proceed to link man with the rest of the animate world, and show how he, too, in his relation to natural environment, and to his animate or social environment, is constrained by the laws of Nature.

The difficulty of finding teachers qualified to conduct biology teaching with these ends in view, leads to the question as to whether the universities have attempted to meet the need for teachers of biology. They should introduce more of the liv animal ; there should be more first-hand cont with Nature, a greater familiarity with Brit plants and animals, their relationships with e other and with man himself. In their glorificat of research, which is often pedestrian in natu and their belittling of school teaching, furt blame must be apportioned to the universities.

Other speakers amplified three main poi which arose from the addresses : the need inculcating the right mental outlook and developing perspective and initiative, and a c demnation of academic biology. During the d cussions, one felt that a genuine attempt is bei made to meet those criticisms of school scien teaching which is contained in the Spens Repo and that a step forward has been made to app hend the possibilities of biology. Prof. F. Brooks, University of Cambridge, suggested th the wide extension of 'refresher' courses in t universities would make a valuable contributi to meet present deficiencies.

The part played by biological education contributing to the welfare of native societies w described by delegates from New Zealand, Au tralia, Africa, Malaya, West Indies, Ceylon a other parts of the Empire. Sir Frank Stockdal agricultural adviser to the Colonial Office, e phasized the need for co-operation betwe education, agricultural and health officers communities that live close to the soil. In mo tropical countries, a bias is already being given education in teaching improved methods agriculture, personal and social hygiene, housin and sanitation. In this connexion the need f an adequate training of teachers in huma biology was stressed by many of the coloni visitors.

OBITUARIES

Maria Ogilvie Gordon, D.B.E.

DAME MARIA OGILVIE GORDON died on June 24, and with her has passed a pioneer in woman's share of scientific education and research. Eldest daughter of the Rev. Alexander Ogilvie of Aberdeen, she received her schooling in Edinburgh. She then, 1889–90, studied at University College, London, where she won the gold medal for zoology and comparative anatomy under Ray Lankester. In 1893 she was awarded the London D.Sc. Meanwhile, 1891–95, she had undertaken an investigation of recent and fossil corals under Hertwig and Zittel at Munich. She could not in those days enter the University of Munich as an official student, but merely as a private research worker, receiving kindly assistance from the professors and others of the staf Under these conditions she published two importan papers on corals, one in the *Transactions of the Roya Society* and the other as a supplement to *Palæonto graphica*. In recognition of their merit, she was i 1900 granted the Ph.D. of Munich with highes honours. The occasion was specially noteworth because it was the first time this degree had bee conferred upon a woman.

Corals led Dame Maria into other fields tha zoology and palæontology. In 1891, she accompanie Baron von Richthofen on a geological excursion t the South Tyrol, and listened to him expounding hi thirty-year-old application of Darwin's theory o atolls to the irregularly disposed Triassic dolomite he region. Afterwards, without losing Richthofen's ndship, she contested his interpretation, and ributed most of the seemingly capricious behaviour the rocks to hitherto undetected thrusts. Those o recall the fate of somewhat similar criticisms of ldeman's reef-knolls in the Carboniferous of Great tain may expect that a considerable proportion Richthofen's conception will survive; but there be little doubt of the permanent value of many Dame Maria's contributions to the palæontology, atigraphy and tectonics of the district. Here we y single out, as specially characteristic, her claim have established recurrences of powerful earth vements with pronounced changes of strike.

n the fastnesses of the Tyrol, Dame Maria suffered m more than the usual isolation of a research rker in field geology, but at home she never lacked -operation in the discussion and presentation of r observations. In 1932, when she received the ell Medal of the Geological Society, she gratefully alled help received from men like Geikie, Topley, pworth, Peach and Horne. Altogether, she pubhed about thirty original works, rather more than lf of them in German. British readers also will ver forget her translation of Zittel's "History of ology and Palæontology" (1901).

Dame Maria, in spite of her scientific activity, und time to take a leading part in advancing the lfare of women and children in general. She rried in 1895, and had one son and two daughters, whom the elder was christened 'Coral'.

E. B. BAILEY.

Sir Henry Stuart-Jones, F.B.A.

WE regret to record the death of Sir Henry Stuart-nes on June 29, aged seventy-two years.

Few men of learning in this generation have mbined so fully the widest and most exact scholarip with academic statesmanship and administrative ive. Best known among students as editor of the vised "Greek Lexicon" of Liddell and Scott, Henry uart-Jones will be remembered among Welshmen principal of University College, Aberystwyth, and ce-chancellor of the University of Wales.

Born on May 18, 1867, and educated at Rossall nd Balliol, he had an academic career of exceptional istinction, and was elected in 1890 to a fellowship t Trinity College, Oxford, to which (after busy years f travel and study in Greece and Italy) a tutorship as added in 1894. He had already taken pupils at xeter College for Henry Pelham. As temporary lief from characteristic overwork, he held from 903 until 1905 the directorship of the British School f Archæology in Rome, without severing his conexion with Trinity; but at the end of 1905 he left xford and settled at Saundersfoot near Tenby, evoting himself mainly to Roman history and ntiquities.

In 1911, however, Stuart-Jones seemed the obvious an to edit a new edition of "Liddell and Scott", hich involved drastic changes of plan and the rganization of wide collaborated research, in which he was ably assisted (1921–37) by the late Roderick McKenzie. This great task remained a central interest for him through life.

After valuable war services to the Foreign Office, Stuart-Jones had scarcely resumed work on the "Lexicon" when the Camden chair of ancient history fell vacant by the premature death of Francis Haverfield. Stuart-Jones could have filled any of the Oxford chairs in classics, ancient history, or archæology with distinction, and his inaugural lecture as Camden professor was a fine piece of research and exposition. But he published nothing further. He lectured mainly on the provincial administration of the Roman Empire, and was lavish of his varied learning to colleagues and advanced students. Though living still at Saundersfoot in vacations, and retaining his editorship of the "Lexicon", he took an active part in college and university business; and his appointment in 1927 as principal of the University College of Wales at Aberystwyth, though surprising to some of his friends, actually concentrated his manifold equipment and exceptional energies into a less diffuse career, though he continued to edit the "Lexicon", and rendered valuable services to the council of the British Academy.

At Aberystwyth, Stuart-Jones's rapid and intimate mastery of academic detail, and his newly won proficiency in Welsh, enabled him to take the initiative in many directions: college-buildings, status and salaries of his staff, courses in arts and crafts, research in agriculture and plant-breeding in the institute endowed by Sir Julien Cahn. He was vice-chancellor of the University of Wales during 1929–1931, and found time for work on the Representative Council of the Welsh Church, and in the Diocese of Saint David's.

His impressive appearance and forcible personality were, however, always ill-served by a delicate constitution; and in March 1934 he found it necessary to resign his academic work. But the "Lexicon", now nearly completed, occupied him still, and the premature death of Roderick McKenzie threw heavy burdens on him in the last two years.

Stuart-Jones was knighted in 1933. All his three colleges elected him to honorary fellowships; he was a member of many foreign institutes, and the Society for the Promotion of Roman Studies celebrated his seventieth birthday with a complimentary volume of its *Journal*, with portrait and bibliography.

J. L. MYRES.

WE regret to announce the following deaths:

Brigadier-General the Hon. C. G. Bruce, C.B., M.V.O., leader of the Mount Everest Expeditions of 1922 and 1924, on July 12, aged seventy-three years.

Prof. W. A. Jolly, professor of physiology in the University of Cape Town and past president of the Royal Society of South Africa.

Prof. John Mellanby, F.R.S., Waynflete professor of physiology in the University of Oxford, on July 15, aged sixty years.

NEWS AND VIEWS

Prof. R. D. Haworth

As announced elsewhere in this issue (p. 168), Dr. R. D. Haworth, lecturer in chemistry at King's College, Newcastle-upon-Tyne, has been appointed professor of chemistry in the University of Sheffield after graduating at the University of Manchester in 1919, and spending some time there working with Prof. Lapworth. Dr. Haworth, having been awarded in 1921 the distinction of an 1851 Exhibition, proceeded to Oxford, where he began his work with the late Prof. W. H. Perkin, jun., on isoquinoline alkaloids, leading to the synthesis of cryptopine and protopine; and to important derivatives of the apomorphine series. This work received the well-merited recognition of the doctorate in science from Manchester in 1930. Since 1927 Dr. Haworth has been a member of the staff of the Chemistry Department of King's College, Newcastle-upon-Tyne, in the University of Durham, where, besides carrying on his work on alkaloids, he has had marked success in the investigation of naturally occurring derivatives of phenanthrene. In this connexion his general method for the synthesis of phenanthrenes has had a wide application. During recent years he has added materially to our knowledge of the structure of natural phenolic resins. He has displayed abilities of a high order as a teacher, both of undergraduates and research students, and has, for some years, been senior tutor in science. Besides these academic interests, Dr. Haworth is a keen and accomplished cricketer. He leaves behind him at Newcastle a host of friends won by his sterling qualities, and their good wishes go with him to Sheffield for the future.

Mr. T. E. Wallis

Mr. T. E. Wallis, reader in pharmacognosy in the University of London, has been awarded the Hanbury Medal of the Pharmaceutical Society of Great Britain. Mr. Wallis has contributed thirty-seven papers describing original work to various scientific societies and their official organs. Roughly speaking, his work can be divided into six parts: (*a*) to discover those details of gross morphology and of microscopical structure by which it is possible to identify correctly vegetable materials used in medicine or as foods or spices either in the entire condition or in the form of powder; (*b*) to provide characters by which adulterants can be detected in foods and drugs, especially when in the powdered form or in broken pieces; (*c*) to discover general methods by which the proportions by weight of powdered materials—drugs or foods—may be accurately determined by means of the microscope; (*d*) to devise improved optical apparatus and mechanical contrivances for use with the microscope in the study of food, drugs and powdered substances; (*e*) the production of books for the use of food analysts and the instruction of students of food and drugs; (*f*) to devise new methods for the determination of the purity of certain chemi substances used in medicine and pharmacy. Wallis's work has extended over the past thirty-n years, and its effect as a whole has been to mak much more possible to maintain an efficient cont over the purity and quality of food and dru especially when in the form of powder. The Hanb Gold Medal is a memorial to Daniel Hanbury w died in 1875. It is awarded periodically for "h excellence in the prosecution and promotion original research in the natural history and chemis of drugs". The Committee of Award comprises presidents for the time being of the Chemic Linnean and Pharmaceutical Societies, the chairm of the British Pharmaceutical Conference, and o pharmaceutical chemist.

Political and Economic Planning

A broadsheet (No. 149) recently issued by P E (Political and Economic Planning) gives a br review of the social and economic surveys whi have already been made by P E P or other agenc or are still in progress. The research group of P E which has already issued a report on agricultu research in Great Britain is now engaged in a surv of British scientific research in general. By th group research activity has been classified under fo main headings: background research, or the pursu of knowledge for its own sake; basic research, the study of broad subjects with a pronounc practical bearing; *ad hoc* research or the study specific practical problems; and pilot or develo ment research, bridging the gap between survey experiment and practice. Social or economic surve generally fall into the second or third group, whi studies of housing problems or of opportunities f industrial development appear to be comparable w such types of *ad hoc* research as the control of foc and-mouth disease. Broader studies of the inciden of poverty or of the factors determining the locatic of industry fall into the same category as the stu of animal genetics.

A feature of the position is the lack of security f the personnel concerned in social and econom surveys, as well as the serious absence of provisic for recruitment and training and for the publicatic of results. Moreover, much of the survey work regarded as compromised by excessive concentratic on immediate practical questions and by a failure develop tested fundamental questions as a chec upon passing fashions of thought. The question co-ordination in the organization and scope of futu surveys is urgent. Voluntary surveys are likely i future to consist chiefly in supplementing or inte preting the more voluminous and basic offici surveys, except in pioneer fields, although even he more systematic methods are required. The educational aspects of survey work also require great attention, both from the point of view of using the results in educating local or national opinion and from that of training personnel. Notes on the more important recent surveys are included.

Air Raid Defence

In the June number of *Air Raid Defence* the nature of the air threat is critically examined, including the factor of increased numbers of aircraft, the costs involved, the method of attack and the functions of the incendiary bomb and the gas bomb, as well as of the high explosive bomb, which is considered to be the main weapon of attack. London is regarded as the most probable target in the lightning attack, although key strategic points such as the steel-making district of Sheffield might also become main targets. Civil defence, it is emphasized, differs entirely from traditional defensive strategy in which the war effort is developed as the war progresses in that the maximum demand will be made of it on the very day that war breaks out. Our organization must be ready to operate effectively immediately peace is despaired of, not a few weeks, or even a few days after war has begun. Moreover, since the lightning attacks are only likely to be delivered for a few weeks, short-term measures are entirely justifiable in our main civil defence scheme. It is wrong to plan on the assumption that the intense pressure of the initial blows can be maintained by the enemy throughout a long war. The parrying of the lightning blow is a problem of imperial strategy; the strategic defence aims at giving the best protection where it is most required. We have hitherto been too much inclined to treat civil defence as a matter for local authorities, with their local responsibilities. What is required is not something for everybody, but a great deal for those who are most likely to be attacked.

Rabbit Control by Virus Infection

Disappointment has attended the latest experimental work of the Australian Council for Scientific and Industrial Research on myxomatosis virus as a means of destroying rabbit populations in the field. On Wardang Island, off the coast of South Australia, a colony of about one thousand adults and as many young, in thirty-three warrens, was built up in a ninety-acre enclosure. The disease was introduced into about half the warrens, and in a hundred days some eight hundred infected animals were collected. Very few warrens not deliberately infected became contaminated. The end result, when the disease had practically disappeared, was almost inappreciable, the death-rate being balanced by the birth-rate. It appears that a sick rabbit leaves its colony, wanders aimlessly away and lives only two to four days. It therefore has little opportunity for infecting other rabbits in its colony, and probably none of giving the disease to other colonies. Thus, although the virus is very virulent indeed, and maintains its toxicity, and although there is no evidence of development of immunity, its capacity to kill off a rabbit population is defeated by the instinctive behaviour of the animal. An insect vector is a possibility that is being explored, though without much hope of success.

Science Review Broadcast

The British Broadcasting Corporation has decided to continue its fortnightly "Science Review", which was begun in January this year. These programmes provide a service of first-hand news from the world of science in a form that is assimilable by the interested layman, and it has the unique advantage of bringing the man of science, whether he is describing a piece of his own research or explaining the significance of an announcement from abroad, into direct contact with his public; and he need fear no false emphasis nor misrepresentation because it is he who does the talking. The programmes last twenty minutes and are usually made up of two separate items, one of which is selected from the physical or mechanical sciences and the other from the natural sciences. In this way they cater for as wide an audience as possible. Some of the more outstanding talks so far have been Dr. B. A. Keen's "What Happens to the Rain" (following on one of the wettest weeks in January and his own presidential address to the Royal Meteorological Society); Dr. P. I. Dee's description of the splitting of atoms of uranium; Dr. E. I. White's talk on the South African 'fossil' Cœlocanth; Dr. Maurice Burton's "Recent Sponge Epidemic in the West Indies"; Donald Carmichael's "How Eskimos Think", and periodic talks on various topical aspects of astronomy by Dr. W. H. Steavenson. If this programme is to retain the standard of interest and topicality it has succeeded in maintaining so far, it must continue to be largely dependent on the co-operation of scientific workers, who are invited to offer suggestions for suitable subjects.

The Science Museum: Acquisitions

A series of interesting transparencies, illustrating recent work of the National Physical Laboratory, on such problems as the accurate measurement of precise components, the determination of the temperature and the pressure of the atmosphere and the speed and direction of the wind during the ascent of a radio-sounding balloon, and recent research in metallurgy, has been set up in the Museum. Photographs of John Fitch's Steamboat Model (1785) have been presented by G. H. Eckhardt, of Philadelphia. John Fitch, of Windsor, Connecticut, is said to have first conceived the idea of marine steam propulsion in April 1785. The steamboat model shown was the first made by him, and was laid before the American Philosophical Society, at Philadelphia, on September 27, 1785. The steamboat was to have been propelled by an endless paddle-chain, which is shown fitted on the port side of the model; on the opposite side is a lee-board. There is no record that such a steamboat was ever tried experimentally. A print of the P.S. *Savannah* (1818) has been presented by the United States National Museum. The *Savannah*, the first vessel fitted with auxiliary steam propulsion to cross the Atlantic, was a three-masted carvel-built ship of 350 tons burden. To aid her spread of sail, she was fitted with an inclined direct-acting low-pressure engine of 90 nominal h.p., constructed by Stephen Vail, at the Speedwell Iron Works, near Morristown, New Jersey. There was one cylinder 40 in. in diameter by 5 ft. stroke. The paddle-wheels were made detachable, so that they could be taken on deck when not in use. The *Savannah* sailed from the port of that name on May 24, 1819; she was off the coast of Ireland on June 17, and arrived in Liverpool three days later. Other accounts state that the *Savannah* arrived in Cork harbour with insufficient coal to raise steam, and that most of her Atlantic crossing was made under sail alone, doubtless with the paddle-wheels on deck. The Museum has also acquired an early machine for covering wires with silk and cotton used from about 1837. It was at one time owned by Mr. W. T. Henley, a pioneer in this field, and was probably made by him. It is still in workable condition.

Roman York: A Recent Discovery

IN the course of carrying out a municipal scheme of improvement, further remains of the fortifications of Roman York have been brought to light, which, it would appear, are part of the curtain wall erected by the emperor Constantinus Chlorus in the fourth century to strengthen the fortifications of the city against the attacks of pirates coming up the river (*The Times*, July 11). In driving an arcade through Coney Street, the remains of an internal tower were discovered which was built astride the wall, and was not external as towers previously revealed had proved to be. Its walls are of dressed stone, and on the south side stand to a height of nearly four feet. On the north side are the remains of what would appear to be a pier of dressed stone, three feet high and connected with the main wall by layers of stone slabs. This is believed to have been either the support of a platform of the tower, or the pier of a bridge, carrying the rampart walk over the interval formed by the tower. Remains of the cobbled rampart walk, with the foundations of another building on the east side, have been found. The position of the tower corresponds with what has hitherto been believed to be the character of the curtain wall, where it ran from the Multangular Tower to the angle tower at the south-east corner of the junction of Coney Street and Market Street. It is the fourth interval tower that has been found.

Anglo-Saxon Burials in Rutland

To a large number of scattered burials forming an Anglo-Saxon cemetery in a pit at North Luffenham, Rutland, belonging to Mr. A. H. Lewis of Morcot, have now been added the graves of a man and woman, in which the male skeleton presents the unusual but not unknown feature in an Anglo-Saxon burial of the period of being in the crouched position (*The Times*, July 11). The grave furniture in this burial consisted of a spear, a pottery bowl, and a large bronze bowl, much crushed. All traces of the woman's body had disappeared, but the grave contained a spindle-whorl, a pot, some beads and a glass bottle. The spear is an unusually long specimen of th 'angular' type, the blade measuring 10½ inches. fragment of the shaft is still embedded in the head The bronze bowl, the most notable object found belongs to a well-known type of the pagan Anglo Saxon period. It is a wide elliptical dish, 16½ inches by 12½ inches, with a depth of about 6½ inches. horizontal projecting flange is about an inch in width and on it is embossed a continuous series of studs The foot ring, of 4½ inches diameter, is cast separately. The bowl has been repaired twice near th rim by the addition of small strips of metal rivete over cracks.

The Golden Gate Bridge, San Francisco

Engineering of July 7 contains the first of a serie of articles on the Golden Gate Bridge, San Francisco. by Mr. C. E. Paine, who acted as principal assistant engineer during its construction. This bridge, which was opened in May 1937, is notable as having the longest suspension span of any bridge yet erected, the length of the span being 4,200 ft. as against the 3,500 ft. of the Hudson River Bridge built in 1931. Its side spans are 1,125 ft. long, giving a total suspended structure of 6,450 ft. The two supporting towers are 690 ft. 4 in. from the top of the piers to the bottom of the saddles and have a combined weight of 35,178 tons, while the wire cables are each over 36 inches in diameter and contain 27,572 steel wires 0·195 inches in diameter, arranged in 61 strands. The roadway across the bridge is 60 ft. wide, giving room for six lines of motor traffic, and there are two side-walks 10 ft. wide. The dead load of the main span per lineal foot is 9·51 tons and the live load allowed for is 1·78 tons per lineal foot. The bridge leads from San Francisco to a district ideal for suburban development and for recreational purposes, and it has closed almost the last break in the two thousand miles long coast road which extends from Canada to Mexico. The American Institute of Steel Construction selected the Golden Gate Bridge as the most beautiful bridge, costing more than 1,000,000 dollars, completed in the United States in the year 1937.

The L.C.C. as an Electricity Consumer

IN a recent paper read before the Association of Supervising Electrical Engineers by Mr. Forbes Jackson, the quantity of electricity consumed by the London County Council and the difficulty experienced in reducing its cost are discussed. The area of the L.C.C. is 116 square miles, and it has a population of more than four million. It consumes approximately for its own services, including drainage, schools, hospitals, fire brigades and administrative buildings, 35 million electric units a year. As this supply is taken from 1,100 different points and from various supply authorities, it is not able to reap the benefit of its great diversity of supply and get an inclusive tariff. This is perhaps the reason why electric supply is not more largely used. Mr. Forbes says that there are only three hospitals which use electric cooking, and its use is not increasing. The L.C.C. deals irectly or indirectly with 1,200 schools, and whilst big programme of conversion from gas lighting to lectric lighting has taken place, the conversion to lectric heating, with the exception of reflector fires n open-air schools, has been slow. The standard adopted for the lighting of schools is 8–10 foot-andles. Mr. Jackson points out that the low ceilings now favoured in modern schools make totally ndirect lighting of class rooms undesirable, for a ow ceiling when too bright has a depressing effect. It is known that the all-electric housing experiments of the L.C.C., of the St. Pancras Housing Association and others have been great successes. During the ast four years, 23,000 houses or flats have been converted from gas to electric lighting by the L.C.C. More than 80 per cent of the tenants had electric ight installed although their rent was raised to meet the cost of wiring.

Preventing Oil Fires in Power Stations

A STUDY of the inflammation of lubricating and similar oils recently made in the research laboratories of Messrs. Mather and Platt, Ltd., Park Works, Manchester, has elucidated the mode of combustion of these oils and led to the development of the Mulsifyre' system of extinguishing oil fires (*Beama Journal* of June). It was found that when lubricating oil was heated in a container to the temperature commonly employed with modern steam turbines, the oil does not take fire. The danger arises when there is a relatively thin film of the oil falling on, or flowing over, a steam pipe. As the oil flows over the hot surface, the complex molecules are 'cracked' and new substances are formed. The heavier fractions remain clinging to the metal surface, while the lighter fractions volatilize. Between these volatilized fractions and the oxygen of the atmosphere an exothermic reaction takes place causing a considerable increase of temperature, and new substances appear, aldehydes, acetic acid, bituminous matter and saponifiable oil.

IT was found that whilst the open flash point of the oil used was greater than 400° F., the flash point of the volatile fractions was only about 175° F. When ignition takes place in these circumstances it never does so at a point in contact with the steam pipe. The flame can often be seen to develop in the air several inches above the pipe. In order that the oil spurting from a defective pipe joint may catch fire, it must be sprayed in the air in a finely divided form. The underlying principle of the 'Mulsifyre' system of quenching oil fires is to change the nature of the liquid. By emulsifying it, the inflammable liquid becomes incapable of burning. With the 'Mulsifyre', the mechanical agitation is provided by discharging water under pressure through a special form of nozzle on to the surface of the oil. The water, issuing from this projector in a strong, driving, well distributed spray, it strikes the oil with considerable force. The projectors are effective either when quite close to the oil or when many feet away from it. A large-scale demonstration plant has been erected at Park Works, Manchester.

The Universal Decimal Classification

MANY classifications have been evolved rather as an intellectual exercise than with any specific aim in view. Others have been made in the attempt to devise a so-called logical system. Most have lapsed already into obscurity. The success of the Decimal Classification, which has survived sixty years of test and is still being adopted at an increasing rate, is a testimony to the qualities inherent in its structure and order. No alternative has been found to be sufficiently valuable to justify detailed development to the extent which the Dewey Classification has experienced, and no classification which lacks such detailed expansion is capable of replacing the Universal Decimal Classification. This classification was adopted unanimously as the international standard classification by representatives of more than forty Governments at the World Congress of Universal Documentation held in Paris in 1937. The Classification is employed in thousands of institutions throughout the world for the indexing and arrangement of public and private archives, books, references to published articles in literature and documents and apparatus of all kinds. Some 150,000 published references to literature in the field of science and technology alone are classified annually in accordance with this code, besides many hundreds of thousands of items in private files. The total work will comprise about 2,000 pages of printing in double column, including about 70,000 classes, and costing about £6. The appearance of "Section 54, Chemistry" (London: Messrs. Simpkin and Marshall, 1939. 7*s.* 6*d.*) will be welcomed by all those concerned with the progress of bibliography. The new Section comprises pure and theoretical chemistry. The industrial processes for the manufacture of chemicals will appear as Section 66. The present section contains about 4,000 main clauses, capable of dealing, in the minutest detail, with every aspect of modern chemistry; as an example of its application may be mentioned the Royal Dutch Petroleum Company, which utilizes the classification to index annually some 120,000 items, mainly of chemical interest.

Evolution of the University Clinic and its Laboratories

Two lectures were delivered by Prof. Simon Flexner at Oxford early in the present year, in which he traced the establishment of clinics in medicine and surgery on a university basis. He suggested that this involves three factors: (1) the provision of laboratories in the clinic for scientific research, (2) the appointment of clinical professors qualified in at least one subject of medical research, and (3) the power of these professors to command time for the patients from whom the research problems are derived. The key to the achievement of these conditions, Prof. Flexner considers, lies in laboratories attached to the clinics, where investigator and student meet and labour together, and he proceeded to review the history of the development of such laboratories. The establishment of clinical laboratories was traced back to John Hughes Bennett and Lionel Smith Beale in the middle of last century in Britain, to Frerichs and Traube in Germany, and to Bowditch and Newell Martin in America. In conclusion, a tribute was paid to Lord Nuffield who, in making his wise and munificent benefaction for medicine, recognized the need to aid the pre-clinical, as well as the clinical, laboratories. The lectures constitute a valuable history of the subject, and have been issued in pamphlet form by the Clarendon Press, Oxford.

Currents in the South Pacific

AN atlas has been constructed by the Marine Division of the Meteorological Office from observations made by merchant vessels and H.M. ships during the period 1910–1937 (H.M. Stationery Office. 7*s*. 6*d*.). No previous atlas of the currents of this ocean has been published since 1897. The new atlas is a definite contribution to our knowledge of the surface drifts of the oceans, for this is the first time that the currents of the South Pacific have been treated statistically. Two charts are given for each quarter of the year. One shows the mean set and drift for each of the small areas where observations are available; the other chart gives roses showing the percentage frequencies of current in any direction for larger areas. In addition, the percentage frequencies of currents, flowing in the same direction, of various strengths, are indicated. In this manner all possible information as to the variation of current is graphically illustrated. The investigation into the currents of this ocean has brought out many important points which are summarized in the text, tables and graphs.

Objectives of Higher Education in India

REFERENCE was made in NATURE of May 6, p. 757, to an article in *The Mahratta* about a proposal for the establishment by the Bombay Government of a Deccan College Institute for higher education in mathematics, philosophy, English, philology, Indian languages, history and economics. The paragraph in question concluded: "In view of the growth of unemployment among the educated classes . . . the comment suggests itself: higher education for what?" The writer of the article has taken exception to these words as implying "a desire to restrict the functions of universities to utilitarian subjects only". They were, in fact, meant to call to mind the danger of promoting educational undertakings without a clear sense of direction and purpose. The whole subject of the unemployment of university graduates is dealt with by W. M. Kotschnig in his "Unemployment in the Learned Professions" (Oxford University Press, 1937). In his survey of the problem in India, he points out that unemployment is worst amongst graduates in liberal arts courses and that this is traceable to a wrong emphasis in education, too much stress being laid on higher literary and theoretical studies. A proposal to establish a new college providing liberal arts courses for graduates appears to call for an answer to the question whether these courses are likely to qualify not merely for the conferment of higher degrees but also for careers which are not already overcrowded.

High Resistance Resistors

THE Zenith Electric Co., Ltd., Villier
London, N.W.2, has issued a catalogue d
its wire-wound vitreous embedded resist
sistances). They consist of a ceramic tub
spirally wound with resistance wire and e

yphus Fever in the United States

IN a recent communication to the permanent com-ittee of the International Office of Public Health ull. *Off. internat. d'hyg. publ.*, 30, 1780; 1938), rgeon-General H. S. Cumming stated that endemic phus transmitted by fleas, as distinct from classical phus transmitted by lice, of which no case had curred in the United States recently, was on the crease in the United States, where three thousand ses had been reported in 1937. In addition to an crease in the number of cases, there had been an xtension of the disease into the interior of the ountry from its original foci on the Atlantic coast nd Gulf of Mexico. Typhus was now being notified the north of Alabama and Georgia and in Tennessee. n recent years, endemic typhus had shown a tendency o spread from the towns to the rural areas, especially hose in which pea-nuts were grown on a large scale, hich suggested that the grey rat, a well-known eservoir of the disease, was being attracted into the ural districts by this kind of food. Another reservoir f the disease was a native rodent known as the ldfield mouse, and about a dozen other native odents which had been found to be susceptible to nfection by typhus were potential reservoirs of the isease. The case mortality of endemic typhus is elow 5 per cent, most of the deaths occurring in atients more than fifty years of age.

The National Research Council of Japan

THE report of the National Research Council of Japan, volume 2, No. 7, covering the period April 1937–March 1938, lists the serial publications issued during this period and includes notes on the general meeting of the Council and on divisional and committee meetings as well as on the international scientific meetings at which the Council was represented. Discussions at meetings of the Committee on Pacific Investigation have dealt with fishes of the Pelew Islands, the fluctuation of water temperature in the north-eastern sea region adjacent to Japan of the North Pacific Ocean, the vertical distribution of plankton in relation to submarine illumination and temperature, the propagative protection of the few seal in the North Pacific. Discussions at meetings of the Committee on Engineering Research have covered television, the technical development of the broadcasting service and the research problems of electric arc welding. A full list of officers and members of the divisions and committees is included with a list of serial publications received from abroad and a table of serial publications already issued by the Council.

Contraceptive Advice by Local Authorities

THE Family Planning Association directs attention to the fact that the Ministry of Health has during the last nine years issued four memoranda to local authorities in England and Wales on the provision of contraceptive advice for married women, but states that of 409 authorities so notified less than half have taken any effective action. The Committee on Abortion in its report (see NATURE, June 1, p. 19) stated that the available facilities for contraceptive advice are inadequate and should be extended. The Family Planning Association, which incorporates several bodies that formerly dealt with questions of birth control, now has sixty-six voluntary clinics where advice on birth control and sterility is given to married women. Information on the subject may be obtained from the Secretary of the Association, 69 Eccleston Square, London, S.W.1, and financial support would be welcomed.

International Geological Congress

THE Second Circular for the eighteenth session of the International Geological Congress, London, 1940, has now been issued. The sessional meetings will be held during July 31–August 8, 1940, and the following ten subjects have been listed for discussion: (1) metasomatic processes in metamorphism; (2) rhythm in sedimentation; (3) the geology of iron-ore deposits; (4) the geology of petroleum; (5) the geology of sea and ocean floors; (6) the pliocene-pleistocene boundary; (7) faunal and floral facies and zonal correlation; (8) earth movements and organic evolution; (9) the geological results of applied geophysics; (10) the geology and paragenesis of the ores of lead and zinc. One of these, the geology and paragenesis of the ores of lead and zinc, will form the subject of a symposium to which recognized authorities have been asked to contribute. It is intended to issue these accounts before the Congress and to promote discussion on them at the sectional meetings.

THE Circular contains details of a series of geological excursions covering most of the British Isles, together with a route-map indicating the principal localities to be visited. In all, fourteen pre-Congress and ten post-Congress excursions are offered and a series of guide-books to be presented to the members is in course of preparation. The arrangements for the Congress are now well in hand and upwards of 1,200 geologists from home and abroad have already signified their intention of being present. Sir Thomas Holland has been elected president of the General Organizing Committee and president-designate of the Congress. All communications should be addressed to the General Secretaries, Eighteenth Session International Geological Congress, Geological Survey and Museum, Exhibition Road, London, S.W.7.

Speleologists in South Wales

THE fourth annual conference of the British Speleological Association will be held at Swansea on August 5–9. In the preliminary programme it is announced that the meetings and administrative organization will be housed in the buildings of the University College of Swansea, while the students' hostel has been placed at the disposal of visitors. The Conference will meet under the presidency of Dr. R. R. Marett, rector of Exeter College, Oxford, whose work in the exploration of the Mousterian cave of St. Brelade, Jersey, is familiar to all students of palæolithic man. August 6 will be devoted to cave exploration, when the members of the Association will be divided into two bodies, one, the archæological section, visiting such famous archæological sites as Bacon's Hole, Paviland Cave, in which was found the well-known Paviland skeleton, and many years ago the late Prof. Sollas claimed to have discovered palæolithic painting, the Long Hole and others. Visits to the museum of the Royal Institution of South Wales and the Caermarthen Museum have also been arranged. The second section on this and succeeding days will engage in pot-holing, visiting Dan-yr-Ogof, Craig-yr-Nos, Penwyll, Porth-yr-Ogof, Wills caves, and others, all of noted difficulty of access. In addition to Dr. Marett's presidential address, a lecture will be given by Prof. T. Neville George, professor of geology in University College, Swansea, and a number of papers on speleological subjects have been arranged. The conference will be preceded by a camp at Lamb's Leer in the Mendips, where a camp held at Easter last discovered a new rift chasm, descending to a depth of 260 ft. below ground. This and other discoveries here of the south regional members of the Association will be reported at the Conference.

Announcements

Prof. W. L. Bragg, Cavendish professor of experimental physics in the University of Cambridge, has been elected *correspondant* of the Section of Mineralogy of the Paris Academy of Sciences.

The Royal African Society has awarded silver medals to the late C. F. Massy Swynnerton, formerly director of tsetse research in Tanganyika Territory. Dr. Edwin W. Smith, editorial superintendent of the British and Foreign Bible Society and editor of the Journal of the Royal African Society, and Miss Margery Perham, research lecturer in colonial administration in the University of Oxford.

Mr. Frederick P. Mills has been appointed honorary secretary of the North of England Institute of Mining and Mechanical Engineers, Neville Hall, Newcastle-upon-Tyne, 1.

The first award from the Anna Fuller Fund of New Haven, Connecticut, has been made to Prof. Ernest Kennaway, Prof. J. W. Cook, Dr. C. L. Hewett, Dr. I. Hieger and Dr. William Mayneord, who are all workers in the research department of the Royal Cancer Hospital (Free), London. The prize, which is worth about £1,500, is awarded for a "real and outstanding contribution to knowledge on the subject of the cause, care, prevention or cure of cancer".

The Thirteenth International Congress of Zoology, which should have been held this year at Rio de Janeiro, will take place in July or August of next year. Further information can be obtained from the Secretary-General, 55 rue de Buffon, Paris, 5.

An international course of malariology will be held at the Institute of Malariology, Rome, on July 25–September 20. The fee is 400 lire. Furt
tion can be obtained from the Istituto di
Policlinico Umberto 1, Rome.

A free course on instruction in th
medicine will be held at the Institute for
of Medicine, Berlin, by Profs. Diepgen a
Drs. Artelt and Heischkel on July 25–
information can be obtained from th
Universitätsstrasse 3 b, Berlin, N.W.7.

An International Air Congress will
Stratford-on-Avon during July 8–13, 194
by the Royal Aeronautical Society, at
will be papers and discussions on the tech
of aviation. Further information can
from the Organizing Secretary, Internatio
gress 1940, 4 Hamilton Place, London,

The eleventh Congress of the Interna
against Tuberculosis will be held in B
August 11–September 20 under the p
Dr. Otto Walter. The discussion will be
three principal subjects: (1) the prob
virulence of the tubercle bacillus, (2) th
tuberculosis in subjects more than fifteen
(3) the re-adaptation of tuberculous patie
Further information may be obtained fro
internationale contre la tuberculose, 6

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 159

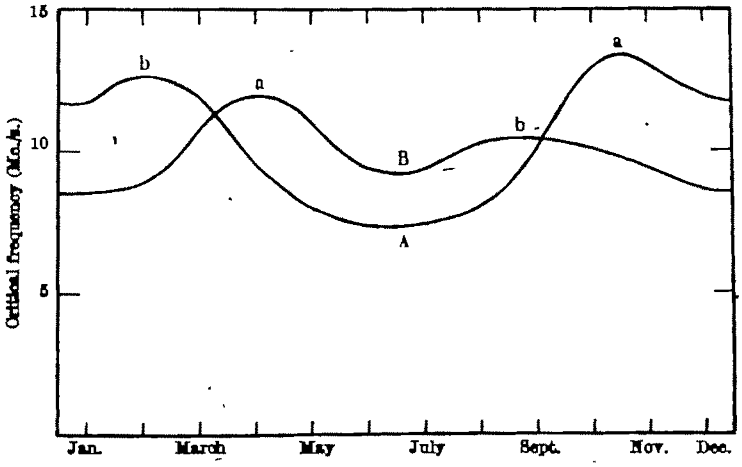
Correspondents are invited to attach similar summaries to their communications.

Characteristic Variation of Region F_2 Ionization Throughout the Year

In a letter from W. M. Goodall, which appeared Nature of June 10, p. 977, there is made one rther step in the elucidation of the complex haviour of Region F_2 of the ionosphere, in that it shown that there is a better correspondence be- reen ionization and calcium flocculi figures for the ntral solar disk than there is between nization and the usual sunspot num- rs. From the determined relation tween ionization and solar activity s expressed by the calcium flocculi gures), it is possible to estimate e average seasonal variation of nization over a number of years, e varying influence of solar activity eing removed. Assuming, for ex- nple, that the solar activity had mained constant at a level ex- ressed by the calcium flocculi char- ter figure 3·0 throughout the period 935–38 (actually, of course, it was radually altering), the seasonal varia- on of the Region F_2 critical fre- uency at Washington (lat. 39° N.) as shown in curve *A* in the accom- anying figure. The trend of such curve confirms the observations f Appleton and Naismith[1,2], who arlier found a similar variation in he northern hemisphere during sunpot minimum at both Slough and Tromsø during he Polar Year 1932–33, and at Slough in succeed- g years. The continuance of the radio work at romsø by Harang[3] has provided further con- rmatory evidence, and we may now feel confident hat a curve of this type represents fairly accurately he seasonal variation of noon critical frequency (and hus ionization) in the absence of marked ionospheric torms.

It will be seen that in curve *A* the two maxima of onization do not occur at the equinoxes, and they may not be associated without qualification, as Mr. Goodall suggests, with the well-known maxima of magnetic activity which occur in March and September. The ionospheric data may now be regarded as sufficiently accurate and extensive for us to be able to say that at the northern hemisphere stations, Tromsø, Slough and Washington, the spring ionization maximum occurs earlier than the spring magnetic activity maximum, while the reverse is the case in the autumn. The maxima of magnetic activity can, moreover, be recognized in the ionospheric data, since in March and September there are found to be the most violent examples of the depression of the critical frequency during ionospheric storms.[4]

Data for the southern hemisphere are not yet sufficiently extensive or concordant for us to be able to specify the variation of ionization with the same assurance as in the case of the northern hemisphere, but from the published data for Watheroo (lat. 30° S.)[5] and from data kindly communicated to me by Prof. F. W. G. White (Christchurch, lat. 43½° S.) and by Dr. D. F. Martyn (Sydney, lat. 33° S.), I have estimated what would be the variation of the critical frequency for a station at lat. 39° S. for the same degree of solar activity represented by *A*. This variation is shown in curve *B*. A seasonal relation is apparent and I suggest that the four maxima in the two curves are correlated as indicated.



Characteristic variation of noon Region F_2 critical frequency for period of constant solar activity. Curves *A* and *B* relate to lat. 39° N. and lat. 39° S. respectively.

(A remarkable feature of the results available to date is that while a variation of the type *A* has been experienced each year since 1932 in the northern hemisphere, the published data for the southern hemisphere station at Watheroo[5] indicate something entirely different. In that case, the (*a*) maximum has consistently occurred in April but the (*b*) maximum has shifted steadily from November to September with increasing solar activity. It will be important to see whether this remarkable anomaly indicated by the published figures is confirmed during the next solar cycle.)

The characteristics of the variation of Region F_2 noon ionization as illustrated by the figure may now be summarized as follows:

(1) The principal feature of Region F_2 ionization is an anomalous seasonal one in that summer ionization is less than we should expect from consideration of the winter value. This may be due to the fact that

the higher atmosphere has a different molecular distribution at high levels in summer and winter, the scale height being increased in summer (such an increase of scale height could result from an increased air temperature or from a reduction in the molecular mass of the ionized air component) or to a seasonal alteration in the type or intensity of the ionizing radiation. This anomalous seasonal effect is most strikingly illustrated by the summer minimum.

(2) There is, in addition, a minimum of ionization in midwinter. This either may be a normal reduction of ionization due to the increased obliquity of the incidence of the ionizing radiation, or may be due to a semi-annual variation of the intensity of the ionizing radiation (photons or corpuscles) arising from the fact that the two sunspot regions north and south of the equator are more directly exposed to the earth at the equinoxes than in summer and winter[5]. In the latter case, it is seen that the influence of the summer minimum mentioned in (1) would tend to make the semi-annual maxima occur earlier and later than the spring and autumn equinoxes respectively.

(3) There is a fairly detailed correspondence between ionizing radiation and solar activity as expressed by central zone character figures.

(4) There is also a remarkable asymmetry between the ionization trends in the northern and southern hemisphere, which is perhaps best described as due to an influence which causes a depression in the critical frequency in both hemispheres during the northern summer[6].

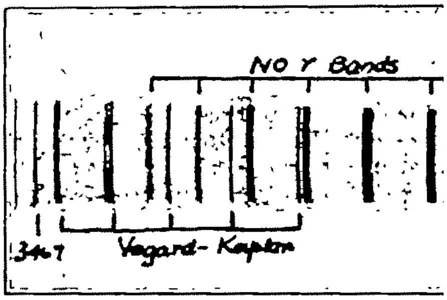
Nitric Oxide in the Earth's Upper Atmosphere

THE failure to observe nitric oxide bands in the auroral spectrum or in that of the light of the night sky has long been a puzzle to me. One of the most conspicuous characteristics of nitrogen afterglow spectra is the intense excitation of the β- and γ-systems of NO in active nitrogen even in the presence of only a trace of oxygen. Of these two systems, the β-bands are the more intense, and the strongest members lie on the long wave-length side of the great Hartley absorption band of ozone. The γ-system lies on the short wave-length side. This description is significant for the interpretation of the experiments which will be described below.

The spectrum which is reproduced here is the spectrum of an afterglow which is produced by passing an extremely weak discharge through nitrogen at a pressure of 10 mm. The nitrogen contained a trace of oxygen, and with a strong discharge showed the strong auroral afterglow which has been studied by me. The spectra of the strong and weak afterglows are as different as those of the aurora and the light of the night sky. The Vegard-Kaplan bands, λ 3467, and the auroral green line are strong in the weak glow and almost entirely missing from the strong glow, which consists of the bands typica spectra. The NO bands are entirely missi strong glow and very strong in the weal The remarkable fact concerning the N the weak glow is the absence of the β-syste the stronger of the two sets of bands. its other features this spectrum represen laboratory reproduction of the light of th so far achieved, we must conclude tha oxide bands are present in the light of th but are not observable because of ozone



Several striking conclusions are inevite that nitric oxide must play an importe excitation processes in upper atmosphere the one which appears to be quite reasoi dissociation of excited nitric oxide by col metastable nitrogen molecules yielding O^1 This is a process which should go on n at higher pressures and thus it leads to the of a very low altitude origin for much of tl from metastable states. This agrees wit observation of λ 2844 as the lower limit sky spectrum. In fact, it would not radical a postulate to suggest that the al low as 25 km., that is, the layer of maxi content.

It may be of interest to point out Compton[2] and his collaborators recentl 25 km. as the altitude at which mesotron took place at a latitude of about 38°. Th the observations reported above, make i to give serious consideration to cosmic ra possible major contributor to the light c sky.

A Determination of the Half-Value P Radium C′ and Thorium C′, with a Time Lags in a Geiger Count

DURING the development of the meth cidence counting for nuclear investig appeared useful to construct a coincider with a variable electrical resolving time provide a method for determining radio value periods of the order of 1 second o basic principle is that if a radioactive placed between two Geiger counters con coincidence counter with resolving time τ the course of successive disintegration, emits pairs of particles which are both detectable by the counters, a genuine coincidence rate of

$$G_\tau = G_\infty(1-e^{-\lambda\tau})$$

will result, where λ is the disintegration constant of the short-lived nucleus.

This method has been successfully applied to the determination of the period of radium C′, and a value of

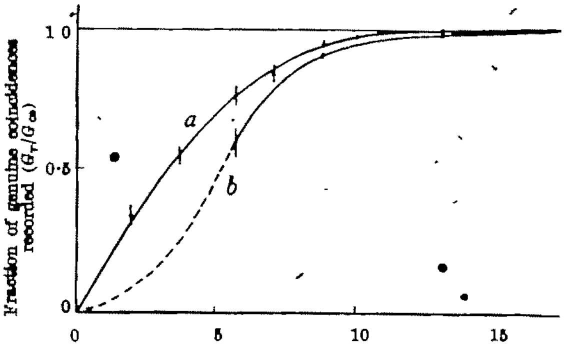
$$1{\cdot}50\,(\pm\,0{\cdot}20)\times 10^{-4}\ \text{sec.}$$

has been obtained for the period, in fair agreement with Jacobsen's determination[3].

The same method of experiment is now being used for a determination of the period of thorium C′. Preliminary experiments yielded curve (*b*) for the variation of the α–β coincidence rate G_τ with the resolving time τ. As a check on the satisfactory operation of the apparatus, experiments were then made with other sources for which no variation in coincidence rate would be expected. None was found (to an accuracy of 1 in 1000) in the range of resolving times 2×10^{-6} sec. to 10^{-3} sec. However, for resolving times below 2×10^{-6} sec. the curve (*a*) was obtained. At this stage, therefore, it became clear that most of the effect with the thorium C′ source, curve (*b*), was spurious. On the other hand, further experiments have shown that the difference between curves (*a*) and (*b*) is really significant, and from this difference a period of

$$3\,(\pm\,1)\times10^{-7}\ \text{sec.}$$

for thorium C′ has been deduced. No previous measurements of the period have been made, but Gamow[4] has estimated it theoretically to be of the order of 10^{-7} sec.



The curve (*a*) has been found to be independent of the source used to provide the true coincidences (for which $\lambda \gg 10^7$ sec.$^{-1}$) and is not materially affected by altering the input capacity of the electrical circuits within reasonable limits. Further, if both valve lines of the coincidence counter are connected to the *same* Geiger counter, each impulse from the counter is recorded as a coincidence by the circuits (for circuit resolving times down to $1{\cdot}5\times10^{-7}$ sec., which is the lowest used so far in coincidence measurements). Clearly the only explanation consistent with all the facts is that the loss of coincidence counts, curve (*a*), must be due to a variable time lag between the formation of the primary ionization inside the counter and the sudden appearance of an appreciable voltage drop across the counter.

This result is qualitatively in agreement with the theoretical suggestions which have been made concerning the action of a Geiger counter[5,6,7]. The time lag which I have observed would correspond to the time taken for an electron formed by primary ionization near the walls of the counter to reach the neighbourhood of the wire, where the electric field is strong and it can give rise to a sudden burst of ionization in the counter. From the present observations, the order of magnitude of this time appears to be 10^{-6} to 10^{-7} sec. The agreement with theoretical predictions is therefore roughly quantitative as well.

It is hoped to publish full details of the experiments very shortly.

Binocular Stereoscopic Vision

PROF. T. S. PATTERSON's recent letter[1] gives further evidence of the principle illustrated in my letter to NATURE[2], namely, that, in binocular vision, the apparent distance, and (consequently) the apparent size of the object, depend on the angle of convergence of the two eyes.

The more general principle—that 'seeing' is a function of the brain, in which our eyes act as scouts but do not themselves draw the picture—may be exemplified as follows.

(1) When we look, with both eyes, at any relatively near object, the retina of each eye necessarily receives a substantially different two-dimensional picture. Yet we do not 'see' a blurred combination of the two pictures, but invent, or rather, model, for ourselves a third well-defined 'stereoscopic' three-dimensional image.

(2) When we move our eyes, so as to take a panoramic view of our surroundings, each retina necessarily receives a moving picture traversing its surface. But what we 'see' is not a moving picture, but successive portions of an extended *fixed* picture.

On the other hand, when a cinema camera performs the same manœuvre, the projected picture shows the scene—whether interior or landscape—revolving relative to the audience.

The fixity of the picture seen when our eyes make a panoramic movement is, of course, due to the fact that we *know* that the external object is *not* moving, and that our brain therefore rejects the retinal evidence of motion which it knows to be illusory. But this process takes time, and if we turn our eyes, or our head, too quickly, for example, if we shake our head rapidly, the outer world appears to shake in the opposite direction.

It would appear that actual measurement of the angular speed at which this illusion occurs might give a measure of the time required by the brain to correct this form of retinal illusion.

It follows that there is a close analogy between normal vision and vision in dreams. The principal difference is that in normal vision the three-dimensional model is built up largely from retinal evidence, whereas in dreams the evidence is wholly, or nearly wholly, provided by the mind of the dreamer.

[1] NATURE, 143, 1026 (1939).

[2] NATURE, 142, 77 (1938).

THE explanation sought by Prof. T. S. Patterson[1] of the apparent reduction in size of the 'squint' stereo-image may be this. The apparent position of the 'squint' image is at the intersection of the crossed optic axes about half the distance of the stereo-card. Meanwhile, the angle subtended by the picture at either eye remains roughly what it was for the 'parallel' image. The inevitable instinctive comparison results in the apparently nearer presenting itself as proportionately smaller.

The reversal of the stereo-photo, left-right, right-left, prescribed by Father O'Leary, does not seem to be necessary. The solid image can be obtained, with or without reversal, as in the stereoscope, so also by direct vision, squint or parallel.

After some not too fruitful experimenting with Prof. Patterson's 'thumb' method, I found it easier to switch from the 'parallel' image by deliberate squint. Then, with a little practice, one can alternate almost at will between the two positions. The accompanying contraction and expansion of the image is most striking. The trick of collimating the optic axes to obtain the 'parallel' image, I am convinced (after years of experimentation upon colleagues and pupils), can be acquired by almost anyone (Old Testament scholars, for some reason, are invariably recalcitrant subjects). The squint habit, I imagine, will prove much more difficult to induce.

An Increase in the Rate of Growth of Paramecium Subjected to the Blastogenic Hydrocarbon 3 : 4-Benzpyrene

IN order to demonstrate a growth-rate larger than the normal, it is necessary to have optimum conditions for growth. If some factor other than the experimental is controlling growth, then of course growth-rate above the normal cannot occur.

Superabundant food was supplied by Peters's medium containing 1,500 million of *Staphylococcus aureus* per c.c. Staphylococcus was chosen because it does not grow in Peters's solution at room temperature, and therefore cannot be stimulated by benzpyrene. Abundant oxygen was provided by growing the cultures, 0·2 c.c. in volume, in shallow well slides. The well slides were kept in petri-dishes containing blotting-paper moistened with tap water. Warm room temperature was used.

The cultures were seeded with about 100 organisms taken from a rapidly growing culture: a rapidly growing culture must be used in order to avoid an initial lag in growth, which occurs when organisms from old cultures are used for seed. Counts were made 24–48 hours after seeding. It is unsafe to count cultures more than 48 hours old because growth rate then begins to fall off owing to exhaustion of food. During 48 hours growth is exponential, and the time from one division to another is about five hours.

The 3 : 4-benzpyrene was applied as a colloidal emulsion in glass-distilled water: to produce, for example, a concentration of one in a million, 0·1 c.c. of a one in five hundred thousand emulsion was added to 0·1 c.c. of a seeded-Peters's-Staphylococcus liquid: the addition of distilled water alone made controls. On account of the strong photo-dynamic action of benzpyrene, all manipulations must be carried out at very low illumination, preferably behind a 2a Wratten filter; and the cultures afterwards kept in the dark. Leaving the cultures at ordinary laboratory illumination, if it does not kill them, greatly reduces their growth rate. When ready for counting, 0·05 c.c. of 'Susa' was mixed into the cultures; after fixation the organisms are no longer light sensitive and can be counted at ordinary illuminations.

Counts of control cultures show some variation, so that sets of four or five pairs were used in all cases.

All these details must be followed for successful experiments. The results obtained in six consecutive experiments are given in the table; in No. 6 sugar was omitted from the Peters's medium; in all cases the dilution of benzpyrene was one in a million.

		Hours of cultivation	Numbers counted	Percentages
1	Benzpyrene Control	24 24	549 467	118 100
2	Benzpyrene Control	30 30	1095 949	115 100
3	Benzpyrene Control	30 30	389 308	126 100
4	Benzpyrene Control	30 30	364 256	142 100
5	Benzpyrene Control	48 48	1363 884	154 100
6	Benzpyrene Control	48 48	773 507	152 100

Benzpyrene was also tested against the non-blastogenic 1 : 2-benzanthracene and gave 115 per cent against 101 per cent, the control taken as 100 per cent. In a single experiment, using benzpyrene in dilutions of one in 100,000, one in a million and one in ten million, the results were 99, 137 and 100. Thus was demonstrated a growth-stimulating property of 3 : 4-benzpyrene on Paramecium in a dilution of one in a million, provided that the cultures were kept in the dark. The method enables one to express quantitatively this action on an animal cell. No attempt has yet been made to estimate the volume of the organisms. In this connexion it may be mentioned that no differences in size between experimental and control were observed.

When benzpyrene is applied to the tissues of animals a localized hyperplasia occurs; from the above results it seems that this is probably due to a direct action on the cells, to growth stimulation.

Distribution of Fluorosis in India and in England

Endemic fluorosis has been described in many different parts of the world. Dental fluorosis is found with waters having a fluorine content of one part per million, and in the United States considerable thought has been given to the elimination of 'mottled enamel' by improving water supplies[1]. Stiff backs and other signs of toxic fluorosis are found when the halogen exceeds three parts per million, and in North Africa, where the amount of fluorine in the soil is considerable, attention has been directed to the agricultural and veterinary, as well as to the human aspects of the problem[2]. Industrial fluorosis among aluminium workers who handle cryolite has been described in Denmark[3]. In Arizona, Smith and others[4] found that fluorine plus diet deficiency was a more potent cause of mottled enamel than fluorine alone.

India. Endemic fluorosis has been recognized among men and animals in the Madras Presidency, and fluorine has been found in the well water[5]. In the adjacent areas of the Nizam's dominions, I, with the assistance of Dr. B. K. Badami, director of Veterinary Services, Hyderabad, found dental fluorosis among children in the Mahubnagar district. The cattle, moreover, in this area develop bone lesions with exostoses, which clinically resemble those found among animals suffering from toxic fluorosis, incurred whilst grazing near aluminium factories in Denmark.

During the past few years I have examined more than 9,000 children in various parts of the Punjab, and in certain clearly defined areas I have found evidence of dental fluorosis in the milk and permanent teeth. These areas include the eastern parts of the Mianwali district, villages near Sargodha, Hundewali near Chiniot, villages around Sangla Hill, in and around Kasur, villages near Ferozepore, and certain villages between Bhiwani and Hissar. I found that the teeth were most 'mottled' among children from the lowest social classes, who showed also irregularity in the size of the individual teeth. Stiff backs and elbows have been observed among village children who used deep well water in the neighbourhood of Kasur[6]. The Irrigation Research Institute, Lahore, at my request, kindly had water from a number of wells in the Kasur area analysed, and obtained from nil to four parts fluorine per million.

All the places where dental fluorosis has been detected in the Punjab are situated on the Indo-Gangetic alluvium, which is of practically the same composition all over the Province, and there is no reason to suppose that this alluvium contains any fluorine[7]. Geodetic research, however, has shown the existence of a ridge of rock causing shallowing of the alluvium[8]. The places from which I have collected records of clinical fluorosis may fairly be said to lie over this buried ridge. Dr. Heron considers it is reasonable to think the rocks forming the ridge may include lavas, and associated granites and rhyolites.

England. Dental fluorosis has been described at Maldon and in certain other parts of Essex[9]. Essex waters have been found to contain fluorine up to six parts per million, and on a visit to that county I found that cases of mottled enamel may be met with in many different areas. Mottled teeth have also been described from parts of Somerset and Suffolk, and have been noted at Ashford, Kent, and at Leicester[10], and in Derbyshire near Chesterfield[11].

At Bampton, Oxfordshire, where I am living while on leave from India, I noticed dental fluorosis in adults and children in different parts of the village. Mr. Ainsworth very kindly came to Bampton and has confirmed my findings. Fluorine has now been found in Bampton well water. I have also recognized numerous cases of dental fluorosis among people who have been born and spent most of their lives in the Marston Valley, Bedfordshire. Analysis has shown that the 'knotts' clay in the Marston Valley has a fluorine content of more than 450 parts per million. We do not know the source of the fluorine in the other parts of England where human fluorosis is found. The brownish-yellow flecks and spots of pigment, together with the dull white opaque areas of dental fluorosis are easily recognized, and if borne in mind, may be noted possibly in other areas.

Dental fluorosis in Oxfordshire. E.G.B. male, seventeen years, born and has lived all his life at Bampton in the Bush. Until the age of thirteen years drank well water.

Insect Size and Temperature

When an insect is reared at graded temperatures, it is commonly found that the size of the resultant offspring decreases with increasing temperature[1]. Evidence of the working of this principle in Nature has emerged in a study of the competition amongst the various organisms which scour and keep open the bacteria beds of sewage works[2]. Four species of these nematocerous Diptera have been systematically measured for eighteen months, the wing-length of the female being taken as a convenient criterion of size. The flies were trapped on the beds of Leeds and of Huddersfield sewage works, where the monthly mean bed temperatures have a range of about

7°–18° C. They were sorted into monthly groups and the standard sample measured varied from 50 to 200 from each of several trapping sites.

Each species measured has a maximum size in one of the winter months and a minimum in one of the summer months with fairly steady intergrading. The extent of the variation is shown in the following data giving the maximum and minimum wing lengths in millimetres recorded in the samples and the percentage difference.

Metriocnemus longitarsus, 2·66 ± 0·010 in January 1939 to 2·01 ± 0·040 in September 1938, 21 per cent difference.

Spaniotoma minima, 1·61 ± 0·007 in January 1939 to 1·19 ± 0·008 in August 1938, 26 per cent difference.

Psychoda alternata, 2·58 ± 0·022 in January 1938 to 1·86 ± 0·016 in June 1939, 28 per cent difference.

Psychoda severini, 2·41 ± 0·012 in January 1939 to 1·89 ± 0·013 in June 1939, 21 per cent difference.

The figures are complicated by the fact that competition, which is most intense in the warmer months, also leads to a reduction in size, and samples taken at the same time from different positions on the beds may vary considerably according to the local composition and density of the population. It is evident, however, that temperature is the conditioning factor and that a rise of 1° C. in the monthly mean entails a reduction in wing-length of the order of 1–2 per cent for each of the four species.

Mr. Glenny Smeal has kindly aided us in the statistical treatment of the data.

The Mexican Loggerhead in Europe

THE valid scientific name of the Mexican loggerhead turtle, described as *Thalassochelys* (*Colpochelys*) *kempi* Garman 1880, is uncertain, since the animal is figured as *Testudo caretta* in the first specific account of a loggerhead[1]. Originally, Linnæus (1758) had conferred this name upon a now unrecognizable form he had attempted to describe by publishing a single family character.

My examination of specimens in 1938 revealed that the Mexican loggerhead is the western sub-species of a monotypic genus, its eastern relative being described in 1829 from the Pacific by Eschscholz as *Chelonia olivacea*. Boettger (1888) and Baur (1890) were the first to record the latter from the Atlantic, and in 1938 I identified specimens from West Africa in the collections of the British Museum and Museum d'Histoire Naturelle, Paris[2].

The costal scutes of the western form are more or less constant and arranged in five pairs; in the eastern sub-species their arrangement is usually asymmetrical, their numbers varying up to as many as nine, on one or both sides. The monotypic genus containing these two sub-species is characterized by four enlarged, pore-bearing inframarginal scutes, separating each side of the plastron from the carapace, and by the olive dorsal colour. The other genus of loggerhead is also monotypic with two sub-species, but possesses only three, poreless, inframarginals on each side and is brown-red dorsally. Both genera differ widely in osteology[2,3].

The two sub-species do not overlap in distribution, consequently the recent discovery that the Mexican loggerhead is washed on to the British Isles[4] has given rise to considerable speculation as to the route and locality whence it arrived. Mr. H. W. Parker, of the British Museum, has suggested[5] that individuals either drift eastwards with the Gulf Stream and West Wind Drift or that the distribution of this turtle is more extensive than is at present known, while Dr. F. S. Russell[6] has suggested that the northward extension of the warm area of the Atlantic might bring these turtles into regions where they could be carried to the British Isles by the surface drift.

The more or less uniform size of the three individuals I identified at the Dublin and British Museums in 1938 suggests that newly hatched young are transported from one and the same locality, and by the time they are stranded off the British Isles have just about reached sexual maturity, although they have by no means attained to their maximum size. The question of the locality whence they were transported is partially answered by my recent discovery of a young specimen from the Azores[7], which supports Parker's view that this turtle possesses a wider distribution than is generally known.

It is probable that while individuals from the Azores travel northward with the extension of the warm area of the Atlantic, and are swept to the British Isles, others are transported from the Gulf of Mexico. Marking experiments both at the Azores and the Gulf of Mexico alone will solve the problem.

P. DERANIYAGALA.

Colombo Museum,
Ceylon.

[1] Schoepff, "Historia Testudinum" (1792).

[2] Deraniyagala, *Spolia Zeylanica*, 18, 61 (1933).

[3] Hay, *Proc. U.S. Nat. Mus.*, 34, 183 (1908).

[4] Deraniyagala, NATURE, 142, 540 (1938).

[5] Parker, *Proc. Linn. Soc.*, 151, 127 (1939).

[6] Russell, NATURE, 143, 206 (1939).

[7] Deraniyagala, *Bull. Institut Océanographique*, 772 (1939).

THE discovery of Kemp's loggerhead in the Azores is of considerable interest, but we obviously still need much more information before we can do more than guess at the causes underlying the movements of these turtles. Among other things, it is essential to discover whether the species is resident around these western islands, for it is quite possible that the single young one found there is a stray similar to those which reach the British coast. The Azores, like the British Isles, lie within the area to which larval eels are carried from their breeding grounds in the western Atlantic. Is it possible that there may be a correlation between the migration of *Leptocephalus* and the movements of these turtles? Or is it a coincidence that 'glass-eels' (larval stage 5) appear off the Spanish coast in September and October, off Ireland in November, and that turtles are stranded on the south-western coast of Great Britain in November and December?

Another point raised which may prove to be significant is the fairly uniform immature size of the examples of Kemp's loggerhead which reach our coast. The three additional specimens examined by

which were washed ashore in 1939 are of the same
neral size as those reported by Mr. Deraniyagala,
d his suggestion thus receives additional support.
his explanation is the correct one, another problem is
sed : Why does not the same apply to the Atlantic
gerhead ? Both species appear off the coasts of the
itish Isles at the same time, and so it appears likely
at both arrive from the same region and on account
the same conditions. But specimens of the Atlantic
gerhead vary from immature individuals of 195 mm.
rapace-length to adults of 900 mm. or more. Have
ults of Kemp's loggerhead a more developed
ming instinct, or are they more powerful swimmers
le to return against winds and currents which the
her species is unable to combat ?

Unfortunately, there is one minor point in the fore-
ing letter which must be challenged. The initial
ragraph, with its implication that the name
studo caretto Linn. should be applied, not to the
lantic, but to Kemp's loggerhead, is misleading.
ne 'species' to which it was originally applied (Linn.
58[1]) was a composite, a fact which its describer
mself realized and tried to correct in 1766[2] by his
oposal of the name *imbricata* for part of his original
retta. This later action was undoubtedly intended
restrict the name *caretta* to one of the loggerheads,
distinct from the Green and Hawksbill turtles
hich received distinctive names.

Unfortunately, no type-specimen has been pre-
rved (if one ever existed), but the locality "ad insulas
mericanas" restricts the possible species to two,
nose discussed above. It is contended by Deraniya-
ala that Schoepff's figure[3] of a turtle named *Testudo*
retta is drawn from a specimen of Kemp's logger-
ead, because, apparently, four inframarginal scutes
re shown (Pl. 16). But it must be pointed out that,
lthough this is undoubtedly true for the right side
f the animal, the left side is depicted as having
hree inframarginals and one smaller scale, a condition
hich is exactly matched by some specimens of
tlantic loggerhead, but which has never been
eported in the other species ! This figure consequently
annot be identified with certainty, and to reverse the
ccepted nomenclature of half a century or more on
uch a slender basis cannot be held justifiable. In
ny event, Schoepff's is not "the first specific account
f a loggerhead". There are many pre-Linnæan
ccounts of these animals, and both Lacépède (1788[4])
nd Bonnaterre (1789[5]) recognized such a form. They
elieved it to be the same species which Linnæus
alled *Testudo caretta* but, for reasons which need not
e detailed here, they preferred the name La Caouanne
r *Testudo caouana* ; as Daudin[6] puts it : "Linnaeus,
Daubenton et d'autres naturalistes ont donné à cette
ortue le nom de *caret* ; mais c'est une erreure que le
rofesseur Lacépède a redressée avec raison, en lui
ubstituant la dénomination de *tortue caouanne* . . ."
The "caouanne" is described as yellow in colour, a
escription which is quite inapplicable to the dark
live Kemp's loggerhead, but which would apply
o specimens of the Atlantic loggerhead.

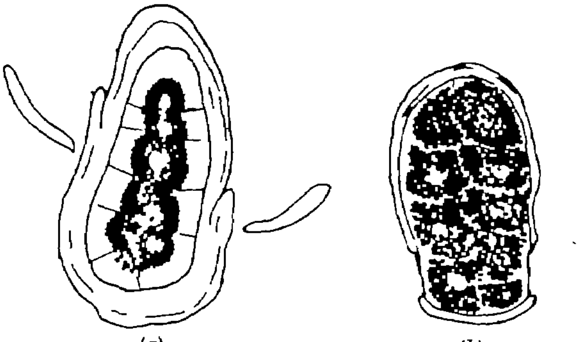
The Colour-Producing Structure in the 'Dominant Grey' Budgerigar

THERE are some distinct structural differences between the feathers of the 'Dominant Grey' budgerigar and those of other races. In the wild coloured form the feathers of the lower abdominal region show in transverse section a somewhat triangular outline, and the vacuoles are arranged along the median axis of the section (see Fig. 1*a*). In the grey bird, the outline appears rounder, and the medulla of the barb is composed of a larger number of relatively small cells, the vacuoles occupying more or less the central parts of the cells and appearing therefore more equally distributed (see Fig. 1*b*).



(*a*) (*b*)

FIG. 1. (*a*) WILD-COLOURED BUDGERIGAR. T.S. OF BARB OF FEATHER FROM LOWER ABDOMEN (×600); (*b*) 'DOMINANT GREY' BUDGERIGAR. T.S. OF BARB OF FEATHER FROM LOWER ABDOMEN (×650).

In the green bird, and also in other races, the melanin granules in the medulla appear concentrated chiefly around the vacuoles. The peripheral part of each medullary cell contains no pigment and forms by its canalicular structure the cloudy medium, producing the basic blue colour. In the grey bird the granules form a rather broad and closed zone around each vacuole. This zone is followed in each cell by a much narrower, cloudy one, which surrounds the cell completely. Thus, in the grey bird the melanin granules do not form a continuous axis in the centre of the medulla. Such an axis would be one of the means of forming a black under-layer, absorbing all rays, except the blue ones. Instead, they are arranged in a more decentralized manner, while the arrangement of the cloudy medium appears not as a broad ring, as in other races, but as a network of narrow stripes.

This arrangement is obviously inadequate to produce an intensive blue shade, the more so since the canalicular structure in the cloudy parts of the cells in the grey feather is a rather imperfect one. It gives in reflected light only a white effect instead of a blue one, and in transmitted light only a buff colour instead of an orange one. This imperfect structure, causing rather dull shades of blue, was first described by Steiner[1] in the races with the factor 'Dark', namely, 'olive', 'cobalt', etc.

Kawamura[2] described in the germ of the green feather a considerable growth of the cell-bodies of the medulla, directed towards the peripheral parts of the section, just before the time of ceratinization and the replacement of the nuclei by vacuoles. During this growth, the nuclei remain in the median region of the barb and thus secure the central arrangement of the vacuoles, shown later in the completed feather. As a modification of this type of development, the medullary cells of the grey feather appear to undergo a more frequent division during growth, and it may be assumed that the growth of the cell-plasm is not limited peripherally.

The structural arrangement of the medullary cells in the grey feather corresponds in general to that of most typical bird-feathers without structural blue colour. The cell-mosaic in the 'normal' green budgerigar, and in many other green and blue feathers, seems to be the outcome of continued growth and retarded cell-division.

Insects in Aircraft

THERE has, during the past months, been talk of an alternative air route, via Africa, to India and Australia. The recent survey flight of the flying boat *Guba* has brought matters a step farther forward, and in the *Daily Telegraph* of June 22 Capt. P. G. Taylor, the pilot, is said to have expressed the opinion "that as all the island bases fulfilled expectations, there was no reason why an air service should not be started at once".

I have been engaged for the past four years upon an investigation into the carriage of insects by aircraft arriving at Khartoum airport, and during the latter part of this period have been studying the question in relation to disease, particularly malaria and yellow fever. The results are shortly to be published in the *Bulletin of Entomological Research*.

In view of the present situation it would seem to be a matter of some urgency to point out certain facts that are perhaps not so widely known or appreciated as they might be.

In Africa and South America the areas of endemic yellow fever have been shown, by means of the mouse protection test, to be considerably greater in extent than was realized, even a year ago. In Africa in particular the area has been extended by recent findings considerably farther east, and according to Findlay[1] may quite possibly be found to extend to the Abyssinian foot-hills.

The discoveries by Shannon, Whitman and Franca[2] of the existence of the virus of 'jungle' yellow fever in the mosquitoes *Aedes leucocelaenus* Dyar and Shannon, *Hæmagogus capricorni* Lutz, and certain Sabethine species, and of the ability of the two former to transmit the virus by bite; and by Findlay and MacCallum[3] of the possibility of infecting monkeys with yellow fever via the alimentary canal, together with the fact that the virus, if introduced into the body cavity of the cockroach *Blatella germanica* L., keeps its activity, at 19° C., for at least 15 days, have lent additional significance to the lists of insects that (*a*) are able to transmit the virus of yellow fever by bite, and (*b*) although unable to transmit by bite, nevertheless retain the virus in their bodies for varying periods of time. These lists are steadily being added to, and the evidence deduced therefrom is reinforced by epidemiological evidence collected during field investigations of recent outbreaks of 'jungle' yellow fever.

The results of recent research upon insects c lected from aircraft have shown a surprisingly lar range of families and species. More than 2,000 a craft were examined at Khartoum airport duri the period July 1935–August 1938. Including u identified specimens, 146 species of insects, numberi 1,960, were collected. If all specimens of *Mus domestica* and *M. sorbens* be included, the total wou be nearly 3,000.

Including *Musca spp.*, the great majority of aer planes contained insects; excluding *Musca spp.* 1 aeroplanes contained insects, distributed fairly even over every month during the three-year period, with slight increase during July–October. The avera number of aeroplanes per month containing insec (other than *Musca spp.*) for the three years was 5·1 with a maximum of 9·5 and a minimum of 1·33. Fo species of *Anopheles*, one of *Theobaldia*, three *Mansonia*, six of *Aedes*, including two *A. aegy* taken at Malakal, and four of *Culex* were found. Th significance of the list is not confined to mosquitoe

In view of the above facts it would seem unwi to start an airline from or via Africa to India an Australia until the problem of the control of insec in aircraft has been solved.

Scientific Research in the Region of Mount Evere

A RECENT communication in the press states tha an Indian scientific worker, Swami Prananabanand is proposing to lead a party of ten scientific investi gators to the Himalayas to study the geology anthropology, botany and geography of the regior He proposes to spend four months on the work at total cost of £300. This news contrasts sharply wit the English attitude towards science in mountai exploration.

As Mr. N. E. Odell recently pointed out in NATUR of April 1, p. 545, the scientific aspects of exploration with the exception of geography, have been sadl neglected by the more recent expeditions to Everest Indeed, it is largely true that "such work . . . ha been in no way encouraged, but rather discouraged, b those responsible both for their organization and thei leadership". From this stricture the Mount Everes Committee itself must be excused, for it has learne from experience that it can best discharge its functions by choosing a leader and leaving everythin except finance to him. As the primary object o Everest Expeditions has been in the past the ascent of the mountain, it is understandable that scientifi observations have been made only with great difficulty.

Expeditions to Mount Everest may have, as some believe, a spiritual significance; they may enhance British prestige; they may be of great interest to arm-chair adventurers. These, however, to 'cut out cant', are not the real motives of the climbers, who go either because it is fun or in order to satisfy a psychological need of a purely personal kind. Though the 1938 Expedition was organized with the most rigid economy and without appeal to public funds, a vast amount of money has been spent in earlier empts to reach the summit. It is questionable ether this expenditure has been justified by the ults and whether even purely private expeditions be excused for letting slip such rare opportunities scientific research. Yet the only permanent ults of past expeditions have been the scraps of ormation gained with great difficulty by geologists, teorologists, botanists, zoologists and physio- ists who have been included in Everest 'teams' ause they happened also to be mountaineers. w much more satisfactory it would be if parties ich failed, through no fault of their own, to reach ir objective, could bring back with them the ults of organized scientific work.

It has been argued that this could be more easily ne on other high mountains. The geology of the erest district must be studied in the district itself, d the same might be said of many other sciences. Of the more general subjects, I am informed that there is no place more suitable for geophysical studies. As for physiology, I am unaware of any place at which a laboratory could be erected at so great an altitude and in such convenient touch with greater altitudes still.

It is possible that many years may pass before the Tibetans allow again within their borders the representatives of a civilization of which they are comprehensibly suspicious. This time might well be occupied by the planning of research and of its financial support, in order that, if and when an opportunity occurs, no time need be lost in putting the plans into operation.

Raymond Greene.

Points from Foregoing Letters

E. V. Appleton illustrates the characteristic varia- n of the ionospheric F_2 region ionization throughout e year by curves of critical frequency for stations similar latitude in both hemispheres. The curves e adjusted to relate to constant solar activity. They ow fairly detailed correspondence between ionizing diation and solar activity.

By studying an afterglow produced by very weak ctrical discharges, J. Kaplan has obtained certain nds of nitric oxide in association with the well- cognized features of the night-sky spectrum. He ggests that much of the night-sky radiation iginates as low in the atmosphere as 25 km. and at the absorption of cosmic rays may be responsible r much of the energy of the light of the night sky.

J. V. Dunworth has constructed a coincidence unter with an electrical resolving time variable in e range 10^{-7} sec. upwards for the determination of nall radioactive half-value periods. The method of periment has yielded values of $1{\cdot}50 \times 10^{-4}$ sec. nd 3×10^{-7} sec. respectively for the periods of dium C′ and thorium C′. Information has also been tained concerning time-lags occurring in a Geiger unter between the formation of the primary ioniza- on in the counter and the appearance of an appre- able voltage drop across the counter.

Sir Richard Paget points out that apparent stance, and consequently apparent size, depend n the angle of convergence of the eyes. We 'see' ith our brains; our eyes are only scouts—on whose vidence (*inter alia*) the brain models its own ree-dimensional image. W. McEntegart states that roduction of a 'squint' stereo-image (without stereo- ope) does not require left-right reversal of the ereo-photograph. The reduction in size of the squint nage, compared to the parallel image, results from e crossing of the optic axes at a point nearer to the server than the object viewed.

The blastogenic hydrocarbon 3 : 4-benzpyrene has en found by J. C. Mottram to increase the growth- ate of Paramecium. Optimum conditions for growth ust be provided. The cultures must be kept in the ark and all manipulations carried out behind a 2a Vratten filter. Stimulation of growth was observed hen the dilution of benzpyrene was one in a million. colloidal preparation of benzpyrene was used.

The distribution of fluorosis in India and in England is considered by D. C. Wilson, and the finding of dental fluorosis in Oxfordshire and Bedfordshire is recorded.

W. H. Golightly and Ll. Lloyd demonstrate a seasonal grading in size in the flies breeding in sewage bacteria beds, the insects being largest in mid-winter. Temperature and competition both influence size, but the former is the conditioning factor and a rise of 1° C. in the monthly mean temperature entails a reduction of about 1–2 per cent in wing length.

P. Deraniyagala records the discovery of a Kemp's loggerhead at the Azores, suggesting a wider distribution for this turtle than has been hitherto known. H. W. Parker discusses the relation of this find to that of other individuals of the species found recently on the coasts of Great Britain. Deraniyagala suggests that there is a doubt as to the valid name for this species, but Parker does not agree that any change is necessary.

According to L. Auber, differences in the colour-shades of budgerigar's feathers are due to the cell structure and distribution of melanin in the barbs. Blue colours are produced by centrally grouped melanin granules reflecting blue due to cloudy peripheral portions of the medullary cells; grey is produced by scattered melanin in medullary cells where there is no large peripheral cloudy area.

F. G. S. Whitfield points out that insects other than *Aedes ægypti* L. have been implicated in the transmission of yellow fever under natural conditions, and that recent researches upon insects collected from aircraft reveal a surprisingly large range of families and species. It is suggested, in view of these facts, that the inauguration of an air line from or via Africa to India and Australia would be inadvisable until the problem of the control of insects in aircraft has been given further consideration.

R. Greene points out that scientific research in the Everest region has been either neglected altogether or pursued under great difficulties during past expeditions to the region. He believes that the time has come for the organization of a scientific expedition.

RESEARCH ITEMS

Causes of Deafness

IT has been estimated that 10 per cent of the population of the United States have impaired hearing. A study of the condition has been made on 487 children in the Pennsylvania School for the Deaf. The investigation was undertaken by the Office of Child Hygiene Investigations of the United States Public Health Service and the Otologic Research Laboratory of the Abington Memorial Hospital. A preliminary account of results is published by Drs. W. Hughson, A. Ciocco and C. Palmer (*Arch. Otolaryngology*, 29, 403). Audiometric records were made for air conduction and also for bone conduction. In a large proportion of cases the diagnosis was hereditary deafness and otosclerosis. A high correlation in auditory acuity between the two ears was found, and sex is not a significant factor. Fifty-four per cent of the children were said to be born deaf. Deafness developing later (generally before six years of age) was attributed to many pathological conditions, meningitis causing 17 per cent and together with trauma of the head, measles, otitis media or scarlet fever accounting for nearly half the cases. There was no apparent association between the auditory threshold and the stated cause of deafness, but the close resemblance between the auditory threshold pattern of children grouped together according to cause and age of onset indicates the importance of the biological constitution as a factor in the causation of deafness. The same authors in another paper (*Human Biology*, 11, No. 2) have made a statistical study of auditory acuity in forty pairs of siblings from the same material. In 70 per cent of cases both siblings were said to have been born deaf, in three cases both were deaf from the same disease, meningitis or whooping cough. The cause of deafness was different in only nine of the forty pairs and the age of onset was different for only nine pairs. Auditory acuity therefore differs significantly less between siblings than between non-siblings.

A Reclassification of the Dragonflies

IN the *Australian Zoologist*, 10, Pt. 2, 30, November 1938, there is published the first part of a comprehensive paper on the above subject by the late R. J. Tillyard. At the time of his death the author was engaged upon a new classification of the order Odonata and had almost completed two parts of this work. It is due to Lieut.-Colonel F. C. Fraser that this contribution has been enabled to be published, since he has corrected it where necessary, added notes and a preface and completed the work so far as has been possible. Although the paper was very incomplete at the time of its author's death, it is abundantly clear that Dr. Tillyard had abandoned his former theory that the whole order Odonata had been evolved from a simple-winged zygopterous type, in favour of one advanced by Prof. Carpenter, who holds that the two sub-orders of dragonflies had an independent origin from zygopterous and anisopterous types respectively. In the new grouping the extinct Protodonata are separable from the Odonata, or true dragonflies, in that they possess a complete series of alternating convex and concave veins, including fully developed posterior media and anterior cubitus. the true dragonflies the two last-named veins usually entirely absent or only short basal remna of them persist in a few fossil representatives. effect, this new grouping removes the Meganeuri from the Protodonata and places them among true dragonflies, with the consequent result that old order Protodonata becomes reduced to a remn with three genera only. To these is added the ger *Palæothemis* of Martynov which forms the s order Archodonata. The position of the Meganeur among the Odonata is that of the most primit group, to which the subordinal name of Meganisopt is applied.

Embryology of Fleas

IT appears that only five contributions have be made to the subject of the embryology of fleas : are brief and fragmentary incursions into the proble Edward L. Kessel, of the University of San Francis has described observations which he has made on t development of three species of these insects whi are of diverse taxonomic affinities (*Smithsonian Mi Coll.*, 98, No. 3 ; 1939). The species were *Cten cephalides felis* of the cat ; the rat flea, *Nosopsyll fasciatus*, and *Hystrichopsylla dippei*, a giant for which lives in nests of the wood rat, *Neotoma*. T actual mode of development proved to be essential the same in these three forms and indicates that the is most probably very little diversity in the proce among fleas as a group. The germ band is partial superficial and partially involuted at the time of t differentiation of the mesoderm. The amnion ar serosa are formed by the overgrowth and fusion the amnio-serosal folds, aided posteriorly by t involution process. Segmentation is evident exter ally towards the end of the third day : a head six segments, thorax of three and an abdomen eleven segments are described. Anterior and posteri mesenteron rudiments are in association with t stomodæum and proctodæum respectively, and t growth of these invaginations pushes the rudimen before them. The latter each proliferate to form tw latero-ventral ribbons and, enclosing the remainin yolk mass, they give rise to the lining of the mi intestine. Sixteen pairs of cœlom sacs are formed– one pair in the antennal segment and in each of the fir fifteen segments posterior to the stomadæal inva ination. The author refrains from drawing any con clusions as to the phylogenetic position of the flea until he has studied personally the embryology c those insects that are suspected of being most closel related to them. Only then, he claims, can it b certain that the same methods and interpretation have been applied to the different subjects and suc comparisons become worth while.

An Inter-generic Hybrid

A SHORT paper by B. O. Mulligan (*J. Roy Hort. Soc.*, 64, Pt. 3, 125–127, March 1939) an nounces the appearance of a fertile hybrid betwee *Gaultheria Shallon* and *Pernettya mucronata*. Th hybrid is a pleasing garden shrub which bear racemes of pearl-white blossoms in June, and the name *Gaulnettya* × Wisley Pearl is suggested for it. Direct crosses between the two species mentioned have never yielded fertile offspring, and the plant at Wisley is apparently a chance seedling. Its morphological and anatomical characters are intermediate between those of *G. Shallon* and *P. mucronata*, whilst seedlings raised from fruits of the hybrid show gradation between the parents. *Gaultheria* and *Pernettya* are at present considered to be separate genera; but the close relationship demonstrated so effectively by this hybrid would be regarded by some investigators as evidence for their union in one taxonomic group.

Leaf Cuttings

Propagation of plants by means of leaf cuttings is often mentioned as a somewhat abnormal method of increase; but it is possible that most evergreen plants would respond to such a means of multiplication. Leaf cuttings from gymnosperms have been struck, and W. Lloyd McCaskie, in a recent short paper (*Gard. Chron.*, June 3, 1939) mentions successful propagation from leaves of several other species. The difficulty appears to be the inaptitude of the severed leaf to produce a bud. Roots are readily formed, and often a considerable amount of callus. Mr. McCaskie has also investigated the part played by this callus. He removed it from leaf cuttings of *Osmanthus Forrestii*, and no buds were formed, whereas a certain proportion of buds appeared on cuttings with normal callus. Young leaves form callus at the base of the petiole much quicker than old foliage. It seems possible that when more practical details are known, propagation by leaf cuttings will offer a very economical means of increase, as the parent plant is not greatly damaged.

Grasshoppers

H. Klingstedt (*J. Genet.*, 37, 389–419) has crossed *Chorthippus bicolor* and *Ch. biguttatus*. The hybrids are intermediate in most characters. The cytological behaviour of the hybrids is abnormal in several respects. The chromosomes are more slender and less contracted, therefore the centromeres of a bivalent may not be brought close together. As a consequence normal disjunction may not take place at metaphase. At anaphase the chromatids sometimes tend to stick together. The author believes that these abnormalities are due to a difference in the timing relationships of the spindle and chromosomes during mitosis or meiosis. Structural changes such as inversions, deficiencies and translocations were indicated.

Crossing-Over Near the Centromere

It is well known that the rate of crossing-over varies along the chromosome. Near the region of the centromere, crossing-over is lower and more variable than elsewhere. K. Mather (*Genetics*, 24, 413–435) uses an ingenious method of showing that low crossing-over is related to position, but variability and sensitivity of the rate of crossing-over to environmental factors is a property of the heterochromatin. Several inversions of the *X*-chromosome which included smaller or larger parts of heterochromatin were genetically studied. These inversions contained genes in a new order relative to the centromere. Whenever the genes were nearer than normal to the centromere, the linkage value was reduced whether or not different amounts of heterochromatin were adjacent to the genes. By treating the flies with heat it was found that the linkage value across a portion of heterochromatin was greatly disturbed, even if the heterochromatin was near the distal end of the *X*-chromosome.

Fruit Pest Control in the U.S.A.

W. P. Flint has recently written an article on the control of codling moth (*Cydia pomonella*) by insecticides other than lead arsenate (*American Fruit Grower*, February). Numerous attempts have been made in recent years to find a substitute for lead arsenate and several substances have been used with some success. Phenothiazine is sufficiently toxic, but its solubility in water renders it almost useless except in arid regions. Cryolite is probably equal in toxicity to lead arsenate but lacks the adhering qualities of the latter. Most success has been gained by the use of various preparations of fixed nicotine. The nicotine volatilizes slowly from these compounds and acts as a stomach poison rather than as a contact poison. Fixed nicotine preparations have the advantage that they contain no substances toxic to fruit or foliage, whilst the percentage of volatile nicotine remains sufficiently high to control aphides to some extent during the growing season. On the other hand, they cannot be combined with fungicides without some reduction in toxicity. Moreover, as their toxicity does not persist as long as that of lead arsenate, more applications are necessary than with the latter. New forms of fixed nicotine are being produced by several different companies under trade brands and are finding a definite place in codling moth control. O. T. Snapp writes in the same journal on the use of ethylene dichloride emulsion as a fumigant for the control of the peach borer. It has several advantages over paradichlorobenzene. It is effective at low soil temperatures and therefore can be used late in autumn and early in spring when it is too cold for paradichlorobenzene to be effective. It is safer on young trees and more effective. The diluted emulsion, prepared by adding nine parts of ethylene dichloride to one part of potash fish-oil soap, may be poured on the soil around the trees or sprayed on the trunks in concentrations varying with the age of the trees.

Evolution of the Earth's Atmosphere

The *Meteorological Magazine* of February, 1939, contains an article by the Astronomer Royal, Dr. H. Spencer Jones, on the evolution of the earth's atmosphere, based on the Norman Lockyer Lecture, delivered under the auspices of the British Association on December 6, 1938 (see also Nature, Dec. 10, 1938, p. 1019). Dr. Spencer Jones begins by explaining how it is that a gas molecule can escape away into space from a planet if it has a radial velocity above a certain critical value which depends upon the force of gravity, and therefore upon the mass and radius of the planet. Jeans has calculated that if this 'velocity of escape' is four times the mean molecular velocity, the atmosphere would be entirely lost in 50,000 years; if five times, the time becomes twenty-five thousand million years. In the case of the earth, the velocity of escape—11·2 km./sec.—is six times the mean molecular velocity of hydrogen at 0° C., which apparently makes the atmosphere virtually immune from loss of hydrogen and still more so for other gases. Nevertheless there is evidence that helium is being lost from the atmosphere. It is believed that this is the result of collisions between atoms of helium with atoms of oxygen that are in a metastable state, whereby the latter unload their energy as kinetic energy and so enable the atoms of helium to acquire a speed of more than 12 km./sec. Another problem is to explain the relatively small amounts of nitrogen and neon in the earth's atmosphere compared with their abundance in the sun and other stars, and the theory is advanced that these and other differences have arisen because much of the original atmosphere was lost into space during the period when the earth was very hot, the present atmosphere being made up partly of the remains of the original atmosphere, from which the lighter gases would have been entirely lost, and partly from gases evolved from the solidifying magma as the earth cooled. Another anomaly, the presence of free oxygen, despite the loss going on in the weathering of igneous rocks, can easily be explained as the result of the break up of carbon dioxide by vegetation.

Tidal Effect on the Variation of Latitude at Greenwich

H. SPENCER JONES has described the method for investigating the lunar tidal effects on the latitude of Greenwich, from the observations for latitude variation made with the Cookson telescope during 1911–36 (*Mon. Not. Roy. Astro. Soc.*, 99, 3; January 1939). From the general formula, which gives the theoretical value of the effect on the variation produced by the semidiurnal lunar tide, the effect for the latitude of Greenwich is easily derived and is $0{\cdot}0077\ (1+\chi)\cos 2t$. The expression inside the brackets takes account of the elastic yielding of the earth, and its value according to W. D. Lambert lies between 1·1 and 1·2; t is the hour angle of the moon. The residuals of the observed minus tabular zenith distances north for each group were used, the total number of plates employed being 4,553, and 24 groups, corresponding to hour angles 0^h to 1^h, 1^h to 2^h, 2^h to 3^h, etc., were utilized. After various corrections the tidal effect, derived from the observations, was expressed in the form $(0{\cdot}0050'' \pm 0{\cdot}0013'')\cos(2t - 2° \pm 15°)$. It will be noticed that the coefficient in this case is smaller than the theoretical value, but the latter is reduced by the rise and fall of the tide in the Thames. A numerical estimate of the effect due to the tides in the river has been made and its amount is $0{\cdot}0021''\cos(2t - 5{\cdot}5°)$. The true lunar effect in the observations is, therefore, $(0{\cdot}0071'' \pm 0{\cdot}0013'')\cos(2t - 3° \pm 15°)$. Comparing this with the theoretical effect, it will be seen that the difference is not of great significance.

Computation of Total Solar Eclipses

FOR about a century, Bessel's method for investigating the circumstances of total solar eclipses has been used almost exclusively. This method is based on the geometry associated with the varying fundamental plane, the normal to which at any instant is parallel to the line joining the centres of the sun and moon. M. Davidson has now described (*J. Brit. Ast. Assoc.*, 49, 299, June) a new method of dealing with the problem, in which the earth's equator is taken as the plane of reference and rectangular co-ordinates are used throughout, the origin being the apex of the cone formed by the tangents to the sun and moon. In this way points on the central line of totality are readily computed. The author gives some comparisons of results obtained by his method with results calculated, as in the *Nautical Almanac*, by the Besselian method. An interesting fact emerges from his discussion; considering the degree of accuracy with which the spherical co-ordinates of the sun and moon are known, Dr. Davidson shows that it is impossible to be certain of the position of the central line to an accuracy greater than about a quarter of a mile when the sun's altitude is about 20°, the uncertainty in the general case being proportional to the cosecant of the altitude. The author proposes, in future papers, to discuss other eclipse problems by his method.

Creatine as a Product of Methylation

C. J. Kelly and H. H. Beard (*J. Biochem.*, Japan, 29, 155; 1939) injected parenterally various compounds containing methyl and methyl-amino groups into young rats to study their influence upon creatine formation and excretion in the body, with special reference to the methylation process involved: 87 control and 105 experimental animals were used in the muscle studies and 44, each of which was its own control, in the urine studies. Their principal conclusions were as follows. (1) Compounds containing methyl groups which were not known to be methylating agents in the body did not influence creatine formation. (2) Those containing methyl groups attached to nitrogen as in methylamine, methyl urea, prostigmin, mecolyl or caffeine increased creatine formation and excretion. (3) Methylating agents, such as methyl alcohol, methylamines, glycolic acid, and paraformaldehyde, also increased creatine formation and excretion. These increases were similar to those obtained from a creatine precursor containing the methyl group. (4) Methyl urea gave the largest increases in creatine excretion of any compound injected. (5) Glycine, by hydrolytic deamination, was converted into glycolic acid, which served as the normal methylating agent for glycocyamine in creatine synthesis in the body.

Oxides and Hydroxide of Gallium

IT was known that gallium oxide Ga_2O_3 exists in two forms and a compound GaO(OH) has been reported, but knowledge of the system $Ga_2O_3 - H_2O$ has been incomplete. A. W. Laubengayer and H. R. Engle (*J. Amer. Chem. Soc.*, 61, 1210; 1939) have made a comprehensive study of the system with the object of obtaining more exact information concerning the phases which occur, their stability ranges and relationships, and their properties. Improved methods of establishing equilibrium with the aid of fused mineralizing agents and of superheated steam in a bomb were used to supplement dehydration studies, and the X-ray patterns of the products were investigated. The existence of the two forms of the oxide and of GaO(OH) was established, and in addition the compound $Ga(OH)_3$, the normal hydroxide of gallium, was established for the first time. This result is of interest since formerly the existence of definite hydroxides of many metals which normally tend to precipitate as hydroxides in a highly hydrous and gelatinous condition was doubted. Many examples of definite hydroxides have lately been established, and the extension of this result to gallium is therefore of some importance.

THE NATIONAL PHYSICAL LABORATORY

ANNUAL INSPECTION AND VISIT OF THE UNIVERSITIES

THE annual inspection of the National Physical Laboratory was held on June 27, when some ,200 technical representatives of industry from all parts of Great Britain met to review the work of the Laboratory and the advances made during the year. The visitors were received in the High Voltage Laboratory by Sir William Bragg, chairman of the Board, Lord Rayleigh, chairman of the Executive Committee, and Dr. C. G. Darwin, director of the Laboratory. Numerous exhibits illustrating the manifold activities of the eight departments into which the Laboratory is divided were available for inspection and demonstration.

This year an opportunity was also provided on July 14 for the staffs and post-graduate research students of the physics, engineering, and related departments of universities to visit the Laboratory. On this occasion the visitors were received by the director, and a programme of exhibits embracing the more academic activities of the Laboratory was drawn up for their benefit.

The following exhibits, noted amongst those on view, illustrate some of the current work done at Teddington.

PHYSICS DEPARTMENT

In the section of the Physics Department concerned with thermal problems a method of measuring the diathermancy of mica and other refractories at elevated temperatures was shown. Black-body conditions are avoided by rotating a disk of the material between parallel heating surfaces in which coaxial eccentric holes permit radiation measurements to be made on the portion of the heated disk which passes between them. The radiation from this portion is measured separately and deducted from the total in order to obtain the transmitted fraction. A method of avoiding convection currents in measuring the thermal conductivity of gases is of interest. The gas is enclosed between concentric cylinders maintained at appropriate temperatures and rotated together at a suitable angular velocity.

The radium or emanation content of feebly active sources such as mineral waters or ores is measured with an alpha ray electroscope. The sample is obtained in aqueous solution and, in the case of radium determinations, allowed to attain equilibrium with its emanation. The latter is then boiled off and passed into an evacuated chamber connected with the electroscope; its activity is compared with that of the emanation from a known quantity of radium.

Extensions to the Acoustics Laboratory have been made to carry out large-scale tests of the acoustical insulation of floors. A room with a massive floating floor has been constructed above one of the sound-transmission rooms. An aperture 8 feet square in the centre of this floor is covered with the sample floor under test, and microphones in the upper and lower rooms enable the measurement of impact and air-borne noises via the test floor to be made. The determination of loud-speaker response curves was also demonstrated. The speaker is mounted in the open, free from any reflected disturbances, and fed with a constant input from a beat-tone oscillator the frequency of which is varied over the whole audible range. A calibrated microphone situated in front of the speaker is connected to automatic recording apparatus which traces the response curve.

An exhibit which has had important practical applications showed the method which has been evolved for the measurement of the temperature of liquid steels, both in the furnace and at various stages after tapping. A high-temperature thermocouple, mounted on the end of a long tilting arm, is provided with a very light silica sheath, and immersed for about ten seconds in the steel. A steady reading is attained within this time, and the thermocouple is then immediately withdrawn. The sheathing will stand up to a number of such quick immersions and is in any event cheap to replace.

X-ray investigations of the structural changes associated with fatigue of metals under a variety of types of stress are still continuing, and work on single crystals is being resumed. Electron-diffraction studies of the surface films of iron and zinc are being carried out in connexion with researches on corrosion undertaken by the Chemical Research Laboratory.

A glimpse of an extra-mural activity in which the Laboratory is now concerned was seen when a cinematograph film illustrating a short-circuit test on an oil-immersed circuit breaker loaded beyond its capabilities was shown. Under an arrangement with the Association of Short-Circuit Testing Authorities, the Laboratory is able to issue certificates on circuit breakers, which may be tested at one of the stations belonging to the Association.

The technique of preparation of high-voltage cable samples for puncture tests under impulse voltages was demonstrated in the High Voltage Laboratory, and the results of such tests were also shown. The layout of the lower stages of a large-capacity impulse generator, utilizing a four-column assembly of the condensers and internal wave-tail and damping resistances, was another exhibit in this building.

In the Photometry Section a comprehensive investigation of the recovery of the eye after transient exposure to a field of high brightness is in progress. The results with white light indicate that, even for foveal vision, a double mechanism of recovery is in operation. The experiments are now being extended to include coloured conditioning and test fields. The measurement of the brightness of a luminescent road sign, mounted on a photometer bench and activated by a 'black' ultra-violet lamp was demonstrated: samples of various fluorescent and phosphorescent materials were also shown.

Apparatus for the preparation of tungsten lamp colour-temperature standards was exhibited. In this work use is made of the fact that incandescent tungsten behaves, within the limits of the visible spectrum, as a 'grey' body. The radiation from a tungsten lamp can, therefore, be colour-matched photometrically with that from a black-body furnace the temperature of which is simultaneously determined with an optical pyrometer. In practice, a substitution method is used in which a comparison lamp is colour-matched first with the black body and afterwards with the standards.

RADIO DEPARTMENT

The meteorological radio-sounding equipment developed in the Radio Department has now been arranged to record atmospheric humidity, in addition to temperature and pressure. A working model of the cathode-ray direction finder designed in this Department for use in marine navigation was an attractive exhibit. The direction of arrival of signals from a model lighthouse and lightship in a marine panorama were indicated on the screen of a cathode ray tube, graduated similarly to a compass dial. The position of the ship on which the visitor was assumed to be standing was hence easily determined from the known positions of the transmitting points. Transmitting equipment for ultra-short wave-lengths was also shown. This consisted of a Class *C* amplifier of 300 watts output working on 2 metres and a frequency doubler with a 50-watt output.

METROLOGY DEPARTMENT

An interesting exhibit in the Metrology Department was an experimental pneumatic slip gauge comparator. This instrument measures the width of the gap between the upper surface of a slip gauge and a fixed orifice by determining the resistance of the narrow gap between them to the flow of air from the orifice. When the width of the gap is changed by substituting a different gauge, the air pressure difference is a measure of the difference in thickness of the gauges. This is measured by projecting the meniscus of a manometer on to a screen, where a movement of half an inch represents a difference of 10^{-5} inch in the thicknesses of the gauges.

A highly sensitive calliper has been developed for use in connexion with the checking of spline gauges for the propeller shafts and hubs of aircraft. The permissible tolerances on these gauges are exceptionally fine. The calliper may be used for pitch and diameter measurements, and incorporates a small smoked glass disk on which the readings are recorded. An image of the disk is afterwards projected at suitable magnification so that errors are readily observed.

Tests on watches and chronometers are made regularly in this Department. The standard clocks used in these tests are checked daily against radio time signals from Greenwich, Paris and Hamburg, and also with the quartz ring oscillator clocks maintained by the Electricity Department. In these comparisons the clocks and the time signals are made to record on a chronograph comparator which is used to measure the small differences in time between the two.

ENGINEERING DEPARTMENT

Several exhibits in the Engineering Department were concerned with the improvement of the accuracy of tensile tests. A set of four secondary standards of ring form which have been calibrated in a dead-weight testing machine have been obtained. These are of a special low-hysteresis steel and their maximum loads range from 3 tons to 150 tons. The load is applied along a diameter of the ring, and the resulting extension or compression is measured by a sensitiv built-in micrometer. By means of these rings th stress imposed by a testing machine may be accurately measured. Good agreement has been obtained in the case of the 100-ton testing machine in th Department, between the stress as obtained b indirect methods and as measured directly on th proving rings. In the course of the indirect determination, the measurement of the knife-edge distanc under load is made by swinging the beam an balancing the rotation imposed on a ray of light by mirror fixed to a beam by an equal and opposit rotation derived from another mirror on a carriag carrying knife-edges bearing on the column and th shackle of the machine. The optical system involve two reflections from the beam mirror, so that th distance between the knife edges on the machine i twice that between those on the optical carriage Improved extensometers for the measurement o strain in tensile tests were also shown. These als employ an optical lever and are arranged for eas calibration by means of slip gauges.

A new electrically heated pipe has been installed for making tests on materials used for pipe lagging 'End effect' has been eliminated by the use o 'guard' heaters 1 ft. 6 in. long at the ends; a third heater 6 ft. long occupies the central portion. The temperatures can be adjusted so that there is n longitudinal flow of heat from the central portion and hence the loss through the lagging may b determined.

METALLURGY DEPARTMENT

Most of the investigations in the Metallurgy Department fall into one of two groups. One is concerned with steels, especially those intended for use at high temperatures as in steam boilers, turbines, and superheaters. The other group deals with alloys of the two light metals, aluminium and magnesium, which are finding increasing applications in the construction of aircraft. The rolling mill is specially designed for work on light alloys, and the slow rolling of magnesium alloys was demonstrated.

The results of X-ray investigations on the age-hardening of single crystals of an aluminium-copper alloy show that the initial stages of hardening consist in the separation of small groups of copper atoms from the mass of the crystals, the groups forming sheets along certain crystal planes. After being formed at a low temperature, a short heating causes them to disappear, and the alloy loses its acquired hardness. Continued heating leads to the formation of larger groups, and the hardness again increases. Finally, a second crystalline phase is produced.

The vacuum creep units designed for experiments in the range 350°–950° C. have been used to study the mode of deformation of pure iron and of steels with various carbon contents. A modified creep unit for the examination of the effect of steam and hydrogen on the deformation of molybdenum and plain carbon steels is now under construction. Apparatus for studying the action of superheated steam on steels under constant stress was also shown. The steel specimens are in the form of hollow thimbles, stressed in tension by the internal pressure of steam, and maintained at a constant temperature by external heating in a regulated atmosphere. After the experiment, the scale formed on the steel is measured and examined microscopically.

AERODYNAMICS DEPARTMENT

The Aerodynamics Department was found to be in tate of considerable activity and expansion. In a t. tunnel the measurement of the flutter derivaes on an aerofoil is effected by imparting an illatory motion to the aerofoil via a nickel tube, d recording the driving torque by an electrical thod which depends on the change of permeability nickel with stress. A systematic investigation of h oscillating forces is in hand, in the first instance aerofoils. A small water tunnel has been conucted for observing the nature of the transition m laminar to turbulent flow. An ultra-microscope ables the flow to be observed in detail by rendering ible extremely minute particles in the water.

The overall stability characteristics of a model roplane are being studied by observing its beviour in a wind tunnel when supported with a tricted number of degrees of freedom. If this thod can be developed to a satisfactory state, it s the great advantage that experiments of this nd can be made in any ordinary wind tunnel and not demand special apparatus. The measurement of gusts has been made for some time on high towers, but this is obviously limited to certain sites and altitudes. A gust recorder which has been designed for attachment to the cable of a kite balloon was exhibited. This will enable a much more extensive exploration of gusts to be made. Difficulties connected with the movement of the supporting cable have yet to be overcome, however.

WILLIAM FROUDE LABORATORY

In the William Froude Laboratory, tests of a model hull fitted with propeller, shafting and internal driving motor were being made in the Yarrow tank. The method of obtaining the propulsive efficiency and the interaction between the hull and the propeller were explained. In the new tank, rolling tests were being made on a model under way, and the effect of various keel and hull shapes on the decrement of the roll was demonstrated. Research on the prevention of cavitation is in progress in this Department, and in the propeller tunnel this phenomenon was exhibited, using stroboscopic illumination controlled from the propeller shaft.

INTERNAL STRAINS IN SOLIDS

A CONFERENCE on "Internal Strains in Solids" was held at Bristol on July 11–13 under the int auspices of the Physical Society and the Unirsity of Bristol. Of the large number of subjects scussed, it will only be possible to mention a few re. Most of the papers presented to the conference ill be published in a special number of the *Proedings of the Physical Society* which it is hoped will pear next autumn.

There was a discussion on the nature of slip in etal crystals. While there was by no means general reement, the following picture of the process uld perhaps find a certain number of supporters: Slip takes place through the passage through the ystal of 'dislocations', in the sense in which the ord is used in the theories of G. I. Taylor, Orowan d Polanyi. The dislocation theory pictures a *rfect* crystal as an elastic medium having the eoretical yield point and no plastic properties; the eoretical yield point is the stress required to pull e plane of atoms over the next all at once, and is any thousands of times higher than the yield oints of hard metals. According to the theory, owever, if the crystal contains any dislocations at ll—and in practice it always does—the crystal will ave a very much lower yield point, because the islocations can move easily through the crystal.

The rate at which a crystal will yield under stress ay be determined, according to Orowan, by one of wo factors: (1) the rate at which new dislocations re formed; (2) the rate at which they move under he external stress. Orowan believes that in general he second factor is the important one, and that the ield point is the stress at which the dislocations ove fast enough to give observable slip.

As regards the origin of the dislocations, it is elieved that they are formed at special spots in the rystal where the stress is particularly high. Thus regularities in the crystal have two roles: to make possible the formation of dislocations, and to hinder their motion. Thus if (1) determine the resistance to glide, irregularities may soften the material, and if (2) determine it, irregularities may harden it. Orowan gives evidence to show that both cases may occur in practice.

It was suggested that glide starts by the formation and motion in a given crystallographic direction of a dislocation of atomic dimensions; but that as soon as the stress reaches the point at which a dislocation can move at all rapidly, the heat developed would cause a dislocation of much larger order of magnitude, giving the macroscopic slip bands observed.

As regards the factors resisting the motion of a dislocation, Peierls' paper shows that a finite stress is required to move a dislocation even in a perfect crystal; thus (in contradiction to G. I. Taylor's hypothesis) a perfect crystal containing just one dislocation should have a finite if small resistance to shear at a low enough temperature.

The much greater resistance to the motion of a dislocation in an age- or work-hardened material must be due to deviations from the ideal lattice. Two hypotheses are possible: (1) that the dislocations are stopped at surfaces of misfit between crystallites; (2) that the motion of dislocations is impeded by the presence of internal strains. (G. I. Taylor's theory makes use of both hypotheses. The dislocations are supposed to be stopped by surfaces of misfit in the lattice; but this does not lead to any resistance to shear, because it is assumed that new dislocations can always be formed at surfaces. The hardening comes from the fact that the strain around the stuck dislocations prevents new dislocations from moving.) If σ_s is the internal shear stress at any point in the lattice, the directions of σ_s will be random. Thus at some points along the length of a dislocation the dislocation will be pushed one way, at other points in another; and for the dislocation to move in a definite direction, the external stress σ must be greater than σ_0 at all points along the dislocation. Hence the observed yield point should be of the order of the mean value of σ_0.

There was a discussion of the mechanism of precipitation of one phase from another, and of the cause of precipitation hardening. Prof. R. Becker emphasized that in alloys in which the degree of supersaturation is small, the time taken to form a nucleus will be long, because a small nucleus will be unstable owing to surface tension, and will usually evaporate before it can grow to a size at which it will be stable. Thus on cooling an alloy, the precipitation is not so rapid on first entering the two-phase region as at a lower temperature where the degree of supersaturation will be greater; and this is so in spite of the very rapid drop in the diffusion rate as the temperature is lowered (cf. R. Becker, *Ann. Phys.*, 32, 128; 1937).

The distinction was emphasized between precipitates which have broken away from the parent lattice and form a new phase, and the smaller nuclei or 'knots' which are formed in the parent lattice, without breaking away. A thermodynamical equilibrium is possible between such knots and the original solid solution, and probably exists in duralumin.

In cases where the two phases have widely differing lattice parameters, it may be impossible for a stable nucleus of one phase to form in the lattice of t other, without breaking away; the energy requi to expand or compress the nucleus is too great, that precipitation would lead to an increase in t free energy. Thus any stable nucleus must alrea have broken away from the parent lattice. It w suggested, however, that the strain energy would less if the nuclei assumed a plate-like shape; a that this might be the cause of the segregation copper atoms on the (100) planes of the alumini lattice observed by Preston in single crystals copper aluminium alloys.

Prof. W. L. Bragg described a theory of t structure of a cold-worked metal. The boundar between the crystallites of a metal must in gene be mobile at room temperature; it was suggest that these boundaries are not frozen in position b are in dynamical equilibrium under their surfa tensions. Thermal fluctuations will cause the boundaries to wave about, and will lead to t gradual disappearance of the smaller crystallit Thus if a metal is thrown into an amorphous sta by cold-working, it will rapidly self-anneal up to certain coarseness of crystallite size, characteris of the temperature, beyond which point crystalli growth should be very slow. According to the ideas, no truly amorphous state is possible in metal.

N. F. M.

POPULATION PROBLEMS OF HOUSING ESTATES

A CHARACTERISTIC of the admirable series of studies issued by the Social Science Department of the University of Liverpool* is their attempt to foresee the problems which social and economic tendencies are presenting to-day and to indicate measures which might be taken either to solve them as they arise or to prevent them becoming too intractable. The latest addition to the New Merseyside Series is no exception. In this survey of the population problems of new estates, with special reference to Norris Green, Mr. Norman Williams indicates the difficulties caused in such districts by a failure in human understanding, together with a serious lack of co-ordination between the different departments of the local authority in the early stages of development. In regard to the provision of schools, for example, the survey reveals grave weaknesses in our present system of local government, an entirely new area with entirely new problems being administered by numerous departments, out of touch with the estate, often acting independantly and sometimes in opposition to each other.

The acute problem of school accommodation in Norris Green resulted directly from the policy of the Housing Committee, but it was left to the Education Committee to solve. Mr. Williams indicates some of the serious consequences of this lack of foresight and co-ordination: the exclusion of children from infants' schools until they were considerably beyond the normal age; the very frequent transference of pupils from one department to a higher; the unusually large classes (up to fifty-six), first in the junior schools and then in the senior schools. Accompanied by these features has been a steady decline in number children seeking admission, which has resulted in steady decrease in the mean age of admission in infants' schools, and it is anticipated that within tw or three years sufficient spare room will be availab in most infants' schools in Norris Green for t organization of nursery classes.

Mr. Williams, however, is not content with direc ing attention to the mistakes of the past and t disastrous consequences of lack of accommodati and large classes for a few children. He is equal concerned with the future. The figures he quot indicate that the big fall in school populati will be accompanied by a big rise in the supply juvenile labour, and since the local demand for labo shows no signs of increasing, a big increase in u employment is to be expected amongst boys a girls. It is pointed out that among male adult unemployment rose from 9 per cent in 1930 to 22 p cent in 1937, the actual increase in numbers bein 550. In 1937 there were about 1,200 unmarried m of more than nineteen in Norris Green, a figure whi is expected to increase to 1,500 by 1942 and 2,1 in 1947. The chances of these men obtaining emplo ment are not encouraging and there is the prospe of about 1,400 of them being unemployed in 1942.

Transport provides another example of a proble created by the Housing Department and left another Corporation Department to solve. T amount of work in the locality is limited and th extra workers, if they obtain employment, must fi it at a distance and will need conveyance. It is doub ful whether the present extended services meet th need, and by 1947 it is possible there will be a increase of more than 50 per cent in those using th combined bus and tram services.

---

* University of Liverpool: Social Science Department, Statistics Division. Population Problems of New Estates, with Special Reference to Norris Green. Pp. 52. (Liverpool: University Press of Liverpool, 1939.) 1s. net.

Equally on the question of housing itself, Mr. lliams points to past mistakes and to errors which quire correction. In the early stages roads were made, there were no shops, several houses were thout light; public halls, cinemas, baths, libraries, d welfare centres found no place in the schemes. ith few exceptions all the houses in the earlier nicipal housing estates have three bedrooms, with e result that there are both empty and over-owded bedrooms even in the same street. To-day Norris Green there is little relation between the uses supplied and the accommodation required. ere is no suitable accommodation for the majority ordinary working-class families of seven persons, d none at all for those of more than seven. Similarly, the absence of accommodation for young couples when they marry is driving them to find accommodation elsewhere. Had the local authority given more attention to the social needs of the people in the early days the number of removals would have been considerably less.

The study shows conclusively the important contribution which the sociologist might make to the rectification of past errors and the prevention of similar mistakes in the future. It is an admirable illustration of the type of study for which there is indeed great need and which might well arrest the attention of scientific workers, as that of the local authorities primarily responsible for the housing estates.

ATMOSPHERIC POLLUTION

THE twenty-fourth report on "Atmospheric Pollution" issued by the Department of Scientific d Industrial Research appears in a new format and two volumes, namely, the report on observations p to March 31, 1938 (H.M. Stationery Office, 2*s.* net) d the other a supplement giving deposit tables over e same period (H.M. Stationery Office, 4*s.* 6*d.* net). his arrangement will be a convenience to those who re interested in the general results rather than the ctual observations. These show that there has een a tendency for the air to become cleaner. Again ardiff provides the lowest figure for sooty matter nd many will learn with surprise that the London rea provides some of the worst figures. Greenwich had he greatest number of days with heavy smoke haze. toke followed next and then Victoria Street, London.

The report contains a section explaining in simple erms how fogs are formed. In Great Britain fogs re said to be caused either by water droplets in the tmosphere or by smoky particles. The water roplets in a fog are only a few thousandths of a illimetre in diameter and for this reason the sun, f visible, appears as a white disk. In a smoke fog, articles are smaller and the sun therefore appears ed because the smaller smoke particles scatter light f shorter wave-lengths but not the longer red wave-engths.

It appears essential, the report continues, in the ormation of fog that the air should contain very small particles on which the water condenses, for xample, sea salt and nitrous and sulphuric acid. The other essential condition for the formation of a water fog is that the temperature of the air must be cold enough for condensation to take place. A high wind may prevent fog, but some wind is essential so that the air can be cooled rapidly.

During condensation fogs, there is usually at a few hundred feet above the ground a layer where the air is warmer than the air below. On a nearly calm day this layer of warm air forms a kind of lid or ceiling below which fog forms. The formation of this layer is an important link between a smoke fog and a water fog.

Smoke escaping from an ordinary chimney is accompanied by hot gases which carry it upwards and the smoke particles may then meet an upper air current which carries them away. If, however, they reach a layer of air which is as warm or warmer than themselves, they cannot escape through this ceiling. If the ceiling is well above the tops of the chimneys and there is not sufficient wind to carry off the smoke, it collects between the ceiling and the ground; we may then get what is known as a 'high fog' where the accumulation of smoke occurs in a layer above the house-tops of the city leaving the air in the streets comparatively clear. Should the level of the ceiling be low enough, smoke accumulation will occur near the ground.

"If," the report states, "we consider the extreme case which might occur, it may make the matter clearer still. Supposing that over a city like London, the wind fails completely up to a height above which the smoke cannot penetrate. The result of this will be that, after a few hours of a winter's day, the city will be covered by a pall of smoke, and this will get darker as the smoke accumulates overhead until the equilibrium is established between the rate at which the smoke particles settle out of the air on to the ground and houses and that at which they are poured from the chimneys. Ultimately, under such conditions the soot fall in the city would be just equal to the soot emitted from the chimneys; but before this condition could be reached, the city would probably be in complete darkness and life might become practically impossible, because not only would the smoke accumulate but also other products of combustion, such as carbon dioxide and sulphur dioxide. Wind is therefore of vital importance as the principal scavenger we have to rely upon to protect us from the smoke which we ourselves produce.

"The smoke fog of our large cities is simply a result of failure on the part of the scavenging forces of Nature, which we rely upon to clear away the smoke, as in the past we relied upon our streams and rivers to carry away our sewage.

"So far as condensation or water fogs are concerned, our cities are less likely to suffer from these than the surrounding country. This is due to two main factors, first that the air over the city is warmer than that in the surrounding country, while the drainage due to the provision for carrying away rain from roofs and streets is such that the ground is very rapidly dried up even after rain and has little opportunity of contributing to the water content of the air in contact with it."

The time is surely past when we should rely on the chance forces of Nature to scavenge our atmosphere and maintain tolerable urban conditions.

FELLOWSHIPS FOR SCIENTIFIC AND MEDICAL R

Leverhulme Research Fellowships

THE following Leverhulme Research Fellowships, tenable for varying periods up to two years, have recently been awarded for the research indicated: T. Burton Brown (Armenian archæology in pre-Christian and early Christian periods); W. H. B Court, lecturer in economic history, University of Birmingham (India and British economic policy in the past century); Dr. W. Cule Davies, lecturer in chemistry, University College, Cardiff (studies of the organic compounds of nitrogen, phosphorus and arsenic); Dr. R. M. Davies, lecturer in physics, University College, Aberystwyth (experimental investigations on turbulent flow in an air-tunnel); R. Dennell, assistant lecturer in zoology, Imperial College of Science and Technology, London (structure and physiology of the luminous organs of Atlantic deep-sea Crustacea); Prof. G. R. Driver, professor of Semitic philology, Oxford (languages and customs of the Semitic East); Dr. R. W. Firth, reader in anthropology, University of London (social structure and economic organization of rural Malays); D. Ll. Griffiths, clinical assistant, Orthopædic Department, Manchester Royal Infirmary (comparison of radiological and histological features in bone tumours); A. E. Ingham, University lecturer in mathematics, Cambridge (analytical theory of numbers); Dr. B. Jones, lecturer in chemistry, University of Sheffield (a study of reaction kinetics in solution); Dr. F. D. Klingender, investigator, Research Group, Political and Economic Planning (a survey of the social relations of scientific research in Great Britain); Dr. S. Maccoby, assistant master, Wolsingham Grammar School, Bishop Auckland, Durham (the character and influence of Radicalism, 1768–1832); Dr. E. B. Maxted, special lecturer in catalysis, University of Bristol (studies in catalyst poisoning); D. A. O'Duffy, research and development assistant, Bahrein Petroleum Company (lubrication problems at high temperatures and pressures); Dr. A. H. Smith, reader in English, University of London (scientific methods of dealing with damaged, imperfect and illegible medieval manuscripts); L. F. Taylor, late research lecturer in Indo-Chinese ethnography and linguistics, University College, Rangoon (an ethnographical and linguistic survey of Burma); Miss M. L. Tildesley, chairman of the Comité de Standardisation de la Technique anthropologique, London (definition, measurements and classification of anthropometric characters); Dr. W. A. Waters, lecturer in chemistry, University of Durham (mechanisms of reactions involving free organic radicals); Prof. E. L. E. Wheatcroft, professor of electrical engineering, University of Leeds (mechanism of development of electric sparks with reference to lightning discharges); Miss D. Whitelock, fellow and tutor in the English language, St. Hilda's College, Oxford (an edition of the Historia Eliensis, Parts I and II).

Rockefeller Travelling Fellowships in Medicine

The following Rockefeller travelling fellowships have been awarded by the Medical Research Council for the academic year 1939–40: G. Blackburn, demonstrator in anatomy, St. Bar
pital, London; Dr. J. C. Dick, assi
University of Glasgow and Glasgow
Dr. J. L. Henderson, assistant, Dep
Life and Health, University of Edin
Illingworth, resident medical assis
pathologist, Hospital for Sick Childre
Street, London; R. M. Kark, forme
in pathology and registrar to medi
Guy's Hospital, London; E. P.
first assistant, Department of M
Postgraduate Medical School, Lond

All these fellows propose to work
United States.

Travelling Fellowships in

The Medical Research Counci
Dorothy Temple Cross Research Fe
following candidates intending to st
tuberculosis at centres abroad, duri
year 1939–40: Dr. R. R. Hen
assistant physician, St. Thomas's H
A. H. M. Siddons, chief assistant,
Department, St. George's Hospita
J. M. Vaizey, medical first assista
London Hospital.

Beit Fellowships

Beit Fellowships for Scientific R
at the Imperial College of Science
during the academic year 1939
awarded as follows: Extensions of fel
satisfactorily held for one year to:
for the continuation of research on c
in relation to hydrocarbon combus
direction of Prof. A. C. G. Egerto
Michiels, for the continuation of
fission of uranium by neutrons, unc
of Prof. G. P. Thomson. New fellow
one year but renewable for a secon
Hatcher, for research on hybrid vigou
under the direction of Prof. W.
Pielou, for research on the olfact
insects, under the direction of Prof
A. L. G. Rees, for research on proble
chemical nature concerned with
germanium, under the direction of
Briscoe.

UNIVERSITY EVI

SHEFFIELD.—The following app
been made: Dr. R. D. Haworth,
chemistry, in succession to Prof.
resigned; Dr. Wilson Smith, to the
logy, in succession to the late Prof.
Dr. Brynmor Jones, at present a lectu
to be lecturer on organic chemistry
as assistant lecturer in geography
Wilson, as assistant lecturer in pha
R. Halle, as a research assistant in
of Glass Technology.

SCIENCE NEWS A CENTURY AGO

Railway Progress in 1839

In its monthly notes on Railway Progress the *Civil Engineer and Architects' Journal* of July 1839 referred to some twenty British lines. It recorded the opening of the Eastern Counties Railway from Shoreditch to Romford on which the rails had been laid to a five-foot gauge "which without greatly increasing the weight of the engines, gives them great mechanical advantages", and the opening of the London and Croydon Railway. Much work was being done on the Birmingham and Derby Railway; an experimental trip had been made on the Manchester and Leeds Railway on which it was calculated "that the expence of travelling in the third-class carriages, which are open and unprovided with seats, will not exceed one penny per mile"; and a portion of the York and North Midland Railway had been opened. By means of this and other lines it was hoped "a direct communication will be opened next year from Newcastle to London". Two further sections of 12 and 8 miles respectively had been opened on the London and Southampton Railway "leaving only eighteen miles, viz., the distance from Winchester to Basingstoke, to complete the whole undertaking".

Maskelyne's Observations at Greenwich

The *Mechanics' Magazine* of July 27, 1839, printed Airy's Report to the Board of Visitors of the Royal Observatory, Greenwich. One section of the report was devoted to the arrangement of the papers at the Observatory. "In my last report to the board," said Airy, "I intimated that it was necessary, before commencing any arrangement of the manuscripts, to divide many of the books into two or more parts. . . . The separation of these parts having been nearly completed, I have been able to proceed with the first step towards arrangement, namely, the marking on the outside of the book the whole of the contents of its interior. From the confused state of some of Dr. Maskelyne's books, this has sometimes been a task of much trouble. . . . I am, however, extremely glad that I have thus been compelled to become acquainted with the system and practice of my predecessors; and my estimation of their judgment and order, as well as their industry has been greatly raised. During the whole, or nearly the whole of Dr. Maskelyne's time, the daily observations of stars are reduced in ledger, and the solstices and equinoxes of each year are discussed, with as great regularity as at the present time; and the same is done with equal regularity, and on a more extended scale, through Mr. Pond's time.

Mexican Mummies

The issue of the *Athenæum* of July 27, 1839, contains the following information: "A million of mummies, it is stated, have lately been discovered in the environs of Durango in Mexico. They are in a sitting posture, but have the same wrappings, bands and ornaments as the Egyptians. Among them was found a poignard of flint, with a sculptured handle, chaplets, necklaces, etc., of alternately coloured beads, fragments of bones polished like ivory, fine worked elastic tissues (probably our modern indiarubber cloth), moccasins worked like those of our Indians, bones of vipers, etc. It is unknown what kind of embalming was used for the mummies above-mentioned, or whether they were preserved by nitrous depositions in the caves where they were found. A fact of importance is stated that necklaces of a marine shell are found at Zacatecas, on the Pacific, where the Columbus of their forefathers probably landed from Hindostan, or from the Malay or Chinese coast, or from their islands in the Indian Ocean."

The Scales of Fishes

"M. Mandl supports the opinion of M. Agassiz that the scales of fishes may serve as characters for classification; and states that these coverings are not to be considered as simply the production of secretion, but consist of a true organised substance. First, he says, that they are composed of an upper and an under layer; then that the upper layer is composed of longitudinal canals, departing from a centre, which is not always in the middle of the scale; of cellular lines produced by the union or fusion of cells; of yellow corpuscles, similar to those of bones and cartilages, and like them containing salts; of a centre or focus which appears to be the rudiment of the scale; of teeth, which, however, only exist on the terminal edge of the Acanthopterygii; thirdly the under layer is formed of fibrous plates, the middle of which are the shortest." (*Athenæum*, July 27, 1839.)

APPOINTMENTS VACANT

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant III (Engineer) at the Fuel Research Station, East Greenwich—Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (quoting J.39/9) (July 24).

Assistant Lecturer in Chemistry—Registrar, University, Sheffield (July 28).

Assistant Master to teach **Mathematics**—Headmaster, Royal Naval College, Dartmouth (July 29).

Established Civil Engineering Assistants in the Roads Department—Assistant Secretary, Establishment Department, Ministry of Transport, Metropole Buildings, Northumberland Avenue, W.C.2 (July 31).

Established Inspectors (10) for the purposes of the Diseases of Animals Act, 1894–1937—Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (July 31).

Assistant Meteorologist in the Meteorological Service, Posts and Telegraphs Department, Sudan—Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1 (August 1).

Lecturer in Physics—Secretary, Technical College, Lansdown Road, Cheltenham (August 3).

Junior Scientific Officer in the Headquarters Office—Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (quoting J.39/11) (August 8).

Assistant Inspectors of Ancient Monuments—Establishment Officer, H.M. Office of Works, Westminster, S.W.1 (August 12).

Assistant Dietitian—House Governor and Secretary, General Infirmary, Leeds (August 14).

Lecturer in Agricultural Chemistry—Registrar, University, Reading (August 14).

Lecturer in Agricultural Bacteriology—Registrar, University, Reading (August 14).

Assistant Lecturer in Botany (Grade III)—The Registrar, University, Liverpool (August 15).

Lecturer in Anatomy—The Secretary, University, Aberdeen (August 18).

Chief Electrical Engineer and an **Assistant Chief Electrical Engineer** under the Government of Bihar—High Commissioner for India, General Department, India House, Aldwych, W.C.2 (quoting Appt. No. 6/49A) (August 19).

Research Assistant—Dr. F. Fairbrother, Department of Chemistry, University, Manchester (August 31).

Assistant Keeper—Director and Secretary, Victoria and Albert Museum, South Kensington, S.W.7 (September 2).

Assistant in Morbid Anatomy in the Department of Pathology—The Dean, British Postgraduate Medical School, Ducane Road, W.12 (September 11)

A **Chemist** and a **Mycologist** at the Long Ashton Research Station—Secretary and Registrar, University, Bristol.

Technical Assistant—Secretary, Air Registration Board, Brettenham House, Lancaster Place, W.C.2.

REPORTS AND OTHER PUBLICATIONS

(*not included in the monthly Books Supplement*)

WHITE SETTLEMENT IN THE TROPICS

T is now more than a century since Sir Samuel Baker recorded his lamentable failure to stablish an English country gentleman's estate in the grassy plains of the heart of Ceylon. His pedigree cattle and sheep soon succumbed and his arefully selected wheat and oats showed early promise, but failed to come to harvest. No less oncerned was his coachman at the death of his arriage horses; with characteristic though misplaced resource, he sought to uphold his master's dignity by teaching an elephant to trot gracefully and so to replace the missing horses. He succeeded only in driving a fine elephant to death. Since hen; many advances have been made in the knowledge of tropical agriculture, yet many of the major problems of white settlement in the tropics and acclimatization to tropical environments remain unsolved.

The problem of finding areas for large-scale settlement of mid-European refugees has thrown nto prominence the need for more accurate knowledge of many of the more sparsely peopled areas of the earth's surface. Those that remain little known are mainly in the tropics. In particular, attention has been focused on British Guiana—in latitude but a few degrees from the equator and thus not very different from the scene of Baker's experiments in Ceylon, and at comparable elevations. In the latter part of 1938, the British Government made a tentative offer of lands in British Guiana as a possible site for the settlement of involuntary refugees created by recent events in Europe. An impartial international commission to investigate these areas was appointed by the President of the United States through the Advisory Committee on Political Refugees. The Commission was a strong one, including members with expert knowledge of health, engineering, colonization, tropical agriculture, soils and malarial control and, with the aid of air reconnaissance, it carried out in the short period February 14 to the early part of April 1939 a remarkable series of journeys, and has presented, with commendable speed, a general report*. A number of appendixes have been grouped together and published† separately, including an important note on the "Possibilities of Agricultural Settlement" by Sir Geoffrey Evans, formerly principal of the Imperial College of Tropical Agriculture at Trinidad.

British Guiana has an area of 89,480 square miles and a population of about 325,000, but the people are concentrated on the sugar and rice lands of the coastal lowlands. The vast interior is virtually uninhabited, save for scattered Indian settlements, mainly in reservations, and occasional mining camps or cattle ranches. The two main areas examined were both south of lat. 5° N.—that is, less than five degrees from the equator—and covered about 30,000 square miles on either side of the Essequibo River. The bulk is covered with dense forest; about one eighth is grassland.

The Commission summarizes its findings by expressing the "opinion that, while the territory is not an ideal place for refugees from Middle European countries, and, while the territory could not be considered suitable for *immediate* large scale settlement, it undoubtedly possesses potential possibilities that would fully justify the carrying out of a trial settlement project on a substantial enough scale that would make it possible to determine whether and how these potential possibilities could be realized".

* Cmd. 6014. (London: H.M. Stationery Office, 1939.) 4d. net.
† Cmd. 6029. (London: H.M. Stationery Office, 1939.) 1s. net.

This is a very guarded statement, and the plan recommended is for receiving camps and trial settlements, directed by properly equipped technical organizations, to be set up at properly chosen locations for some 3,000–5,000 carefully selected young men and women at a cost of about 3,000,000 dollars. The cost is given as a rough figure to be accepted with caution.

It is from Sir Geoffrey Evans's appendix that some clear indications of the possibilities are to be obtained. He emphasizes that the utilization of the open savannah country is essentially a pastoral problem, and that much of the forest country has the light, sandy, easily eroded and easily leached soils common to many of the hot, wet-forest regions of the world. The only areas capable of supporting a permanent agriculture are valley lands of unknown extent in the Kanuku mountains. A difficulty exists that large sections of the savannah country are flooded in the wet season, and drainage might be needed for health reasons; on the other hand, the areas liable to flood seem to support the best pasture. What is envisaged is a compact village community, raising by its own labour subsistence crops on the valley lands, managing cattle on neighbouring savannahs, and thus having not only an assured meat supply but also being able to sell to timber-working communities to be set up in the forest areas, and perhaps to feed a meat packing plant. The scheme incidentally involves the utilization by Europeans of unaccustomed tropical plants as the basis of diet.

It is interesting to note the insistence on the inherent poverty of many, perhaps most, tropical soils; an insistence emphasized by recent work in tropical Australia. There, in complete contrast to the patriotic optimism of only a decade ago, agriculturally utilizable soils have been stated recently to occupy not more than 5,000 acres in the 335,116,800 acres of the Northern Territory. Since the financing of private enterprise in this territory is obviously a concern of the great banks, the Bank of New South Wales recently commissioned Mr. A. G. Lowndes to make detailed investigations on the spot, and then to compare conditions in North Africa, Brazil and other comparable areas. His findings are pessimistic in the extreme: "Beyond the present limits of agricultural settlement, Australia has practically no areas which are definitely known to be suitable for close settlement".

The appearance of the Commission's report postdates by a few weeks the publication as a special

* White Settlers in the Tropics. By A. Gren
tional Notes by Robert G. Stone. (American
Special Publication No. 23.) Pp. xii+311+20
American Geographical Society, 1939.) 4 dollars.

upporting an adequate agriculture, the unknown actor is still, in the main, climate. Ellsworth Huntington contends that there are climatic limits nd optima for human beings as for all other forms of life, and that the tropics are beyond the climatic ptima and near the climatic limits for whites. n a series of long and detailed appendixes to Price's work, Mr. Robert G. Stone, of Harvard, has summarized the present state of knowledge. There are definite physiological changes of temporary and possibly permanent character produced in white peoples by a tropical environment; the real test must come in the second and third generations.

THE IMPACT OF CHRISTIANITY ON SOCIAL AND ECONOMIC LIFE

Christianity and Morals
By Prof. Edward Westermarck. Pp. xvi + 427. London: Kegan Paul and Co., Ltd., 1939.) 21s. net.

PROF. E. WESTERMARCK requires no introduction to the reader; his earlier works on ethics and sociology are well known, and anything that he says commands attention and respect. Several of his previous books have an important bearing on the present volume and in two of these, "The Origin and Development of the Moral Ideas", and "Ethical Relativity", he states his objections to the view of Rashdall and others on the objective validity of moral judgments. The present reviewer dealt with this subject less than two years ago in "Free Will or Determinism", and though his line of attack was somewhat different from that of Westermarck, his conclusions were the same, that belief in the objectivity of our moral judgments is untenable. In "Ethical Relativity", Westermarck argues that the predicates of all moral judgments, all moral concepts, are ultimately based on emotions. There are two moral emotions—moral approval and moral disapproval; the first of these is a form of retributive kindly emotion, and the second is a form of resentment. They are characterized as *moral* emotions, as distinguished from *non-moral* emotions, by the fact of disinterestedness.

In Chapter iii of the present work Westermarck shows that the ethics of Jesus are of a retributive character. It is difficult to read the synoptic gospels without agreeing with this view (John's gospel is in a different category, as few of the actual sayings of Jesus are recorded there). The moral teaching of Jesus is undoubtedly permeated with the principle of rewards and punishments. Although egoistic hedonism has usually been repulsive to the moral consciousness, yet it can have a plausible appearance, and Sidgwick recognizes it as an inevitable element in a complete system of ethics. He defines egoistic hedonism as "a system which prescribes actions as means to the end of the individual's happiness or pleasure". This differs considerably from the egoistic hedonism of the Cyrenaics and Epicureans, and there is nothing in the teaching of Jesus which is contradictory to this definition. In Chapters iv and v it is shown that the teaching of Jesus also emphasizes the disinterested and altruistic character of the moral emotions, and here we see the feature that distinguishes them from other, non-moral, retributive emotions. The Golden Rule brings this out very clearly, although it should be pointed out that this Rule is older than Christianity, and in its negative form is widespread.

There is a very marked contrast between the teachings of Jesus and of Paul. According to Paul, salvation is not a reward for righteous conduct, as Jesus taught, but is entirely dependent on divine grace, "through the redemption that is in Christ Jesus". His doctrine of justification by faith was accepted by the Church from the days of St. Augustine, though Catholicism has always recognized the meritoriousness of good works. The denial of this and the trust in justification by faith alone had very demoralizing effects amongst various Protestant sects, which even Luther himself was forced to admit and bewail. On p. 117 it is stated that Paul had imbibed from his Jewish upbringing the idea of all mankind doomed to death on account of Adam's sin. But the doctrine of 'evil impulse', not associated with the Adam story, was held in official and cultured scholastic Jewish circles, and there is much to commend the view of Dr. N. P. Williams, that the Adam story, held largely in backward Galilee where Jesus did most of his work, was adopted by Paul. This he did out of deference to those disciples, Peter in particular, who had seen Jesus in the flesh, and while it cannot be proved that Jesus in fact accepted the Adam story, yet in some of his sayings he appears to assume a sinful disposition inherent in man.

Nine chapters are devoted to a consideration of the impact of Christianity on ideas and conduct regarding the sanctity of human life (including warfare, infanticide and suicide), economics, slavery, regard for the truth, marriage, divorce, irregular sex relations, and consideration for the lower animals. It must be regretfully confessed that a large portion of this is an indictment of Christianity, and the Christian apologist will find it difficult to defend his position. It cannot be denied that the capitalist spirit influenced theological dogma, more especially in the sixteenth and seventeenth centuries. The attitude of Islam towards slaves contrasts favourably with that of Christianity, which was influenced by false Old Testament teaching. The personal independence enjoyed by the married woman under the later Roman law was lost through legislation influenced by Christianity. This personal independence wa regained, not because of, but in spite of, th Churches. The opposition that the Christia Churches have raised against divorce, even whe innocent people were living under condition compared with which the lot of the slave was happy one, will not be easily forgotten. Repentanc in sackcloth and ashes may be a prerequisite fo organized religion if it entertains any hope o moulding the future of Western civilization.

The work is extraordinarily interesting, an coming from one with Prof. Westermarck' reputation, will command a large reading public It is a little surprising that "The Laws of England" by the Earl of Halsbury, published in 1911, shoul still be quoted relating to the present law o England on marriage, and that no mention should b made of recent legislation. M. D.

CO-OPERATION IN RESEARCH

Co-operation in Research
By Staff Members and Research Associates of the Carnegie Institution of Washington. (Publication No. 501.) Pp. ix + 782. (Washington, D.C.: Carnegie Institution, 1938.)

ON December 31, 1938, Dr. John Campbell Merriam retired from the presidency of the Carnegie Institution of Washington. The volume under review, with its intriguing title, has been written by his colleagues to express to President Merriam "the appreciation felt by the members and research associates of the Institution for his continued inspiring guidance of their work and for his stimulating personal interest in their problems". It is no small task to have directed, for eighteen years, the policy of a great research organization like the Carnegie Institution, and it is possible that, at the last assize, the holder of such an office may be found to have exerted as great an influence on human progress as leaders in other spheres of activity whose names are much more prominent in the pages of the daily press. In this spontaneous tribute from his colleagues, however, Dr. Merriam will, we are sure, find ample reward for his service to science, and through science to humanity.

Commemorative volumes are not invariably—perhaps not even usually—of much intrinsic importance; they tend to belong to the ephemera of literature. "Co-operation in Research" is one of the exceptions. In the first place the responsible committee wisely decided that the papers included should deal with current problems, and should epitomize the activities of the Institution in various branches of science. As there are few branches of science in which the Institution is not active, the volume serves as an admirable conspectus of the present state of knowledge in many fields, and its perusal is a liberal education. Water in geological processes, the surface of the moon, sunspots and stellar distances, universal aspects of atmospheric electricity, eighteen years of research on the gene, "What and Why is Leukemia?", the influence of nutrition on the chemical composition of the normal body, the substance of American history, race and class in Yucatan, ancient forests of Oregon; these are a few topics—chosen at random—to indicate the scope of the volume. Nor are the articles, in spite of their number, in the least superficial Under the rule of Dr. Merriam, a piece of research was not considered finished until its results had been made available, not merely to the specialist in the subject itself but also to specialists in other subjects, and in their simplest form to the public at large. The articles in the present volume show that the members of Dr. Merriam's team have learned their job.

But the volume is something more than a record—it is a confession of faith. "Co-operation in Research" is the title of the book, and co-operation in research was the policy pursued by the Institution under the guidance of its chief. "Throughout his administration," says the foreword, "Dr. Merriam has stressed the need for co-operative attack on problems too large to be solved by a single observer, and has initiated many projects in which teamwork by different groups has been essential to success." The whole book is a tribute to the vital importance of the method, and the individual papers demonstrate, better than pages of argument, the value of co-operative endeavour in science.

This testimony is timely. In large industrial research organizations, no doubt, active co-operation between scientific workers of differing trainings has been, or is being, largely achieved; with results which amply justify the by no means excessive sums spent on the work. Pure science, however, still lags woefully behind. It is by no means easy to break down the partition walls which separate the sciences, and to bring together in equal partnership and in the same laboratory men of different training. It calls for vision and courage; more essentially still, it needs money. Yet there can be little doubt that the next great advances in knowledge are waiting to be made in those neutral territories which separate science from science. In particular, the time is ripe for a mass invasion of the no-man's-land dividing physics from biology: a territory in which neither physicist nor biologist can walk in safety alone. Something is being done, but far less than the opportunity warrants. It is much to be hoped that the considered testimonies to the value of the method contained in this commemoration volume may provide a stimulus to still further efforts at co-operation in research.

J. A. Crowther.

SCIENCE, ART AND DESIGN

The Scientific Aspects of Artists' and Decorators' Materials

By Dr. R. S. Morrell. Pp. xi + 142. (London: Oxford University Press, 1939.) 5s. net.

THE studio of the medieval artist or craftsman was very much more than a place where pictures were painted or pots were fashioned. It combined the functions of workshop and laboratory for the master's own activities, and for the instruction of his pupils. A long apprenticeship was demanded of those whose ambition it was to become master-craftsmen, and much of this period seems to have been devoted to an intense and intimate study of materials, which included the preparation of pigments, and the application of sundry metallurgical principles such as those of metal refining and extraction. In a word, this was a hard school of training in the properties of matter, somewhat far removed apparently from Ruskin's vision of Giorgione as he appears in "The Two Boyhoods".

Farther north, the van Eycks had been experimenting with the behaviour of emulsions and colloids, an adventure which, like many another, led to no startling discovery, no mystic secret, but which produced in the end (after innumerable transitional techniques) the supreme achievement of the Netherlands—the perfection of oil painting.

Nevertheless, the course of man's attempts to obtain the mastery over matter is strewn with failures, instructive but none the less unfortunate. Seventeenth-century Italian pictures executed upon slate supports have revealed an oil film under the paint layer which has brought about disastrous lack of cohesion, with consequent flaking; and the sequelæ of Reynolds' love of bitumen are all too obvious in the havoc which has surely followed upon a lapse from a rigorous appreciation of the laws of physical chemistry.

In our day, a return is noticeable to an interest in materials as such, but the focus of attention is naturally different. The urge is first to understand and then to apply all the manifold new products which synthetic chemistry has provided. Coal-tar derivatives such as monastral blue, substances of high molecular weight like the polyvinyls, bakelite and the rest, are the bricks of which the twentieth-century edifice may be built, and become a thing of beauty.

But with such plenty, the student will ask, "Where shall wisdom be found?" Fortunately, in the modest little book now under review, he can turn to the results of long experience of a teacher and worker in natural science applied to the arts. Dr. Morrell discusses supports, grounds, pigments, lacquers and varnishes not only with clarity, but always with an eye upon the reader who has no intention of becoming a specialist in technological chemistry, but wants to understand the scientific aspect of everyday materials. Yet these pages are no mere compilation of useful properties; they contain a number of sidelights upon art history which are illuminating, as well as necessary for a scholar's appreciation of the development of technique.

In a contribution so excellent, critical comment can only be made with hesitation; yet it is this. The bibliography, adequate as it is up to a point, ignores completely the numerous papers on these very subjects which have been appearing in "Technical Studies" of Harvard University for the past seven years. It seems a grievous pity not to mention them, and perhaps still more, the

"Trial Data" from the same source. Further, no place is found for a reference to the comprehensive work of the Carnegie Institution of Washington on coloured minerals, fundamental for our knowledge of the optical characteristics of pigments.

PURE AND APPLIED THERMODYNAMICS

(1) A Textbook of Thermodynamics

By Dr. F. E. Hoare. Second edition. Pp. xii+307. (London: Edward Arnold and Co., 1938.) 15*s*. net.

(2) Applied Thermodynamics

By Prof. Virgil Moring Faires. (Engineering Science Series.) Pp. xvii+374. (New York: The Macmillan Company, 1938.) 17*s*. net.

(3) Elementary Thermodynamics

By Prof. Virgil Moring Faires. (Engineering Science Series.) Pp. xiii+225. (New York: The Macmillan Company, 1938.) 12*s*. net.

(1) DR. HOARE'S book, which deals with pure thermodynamics, is one of the most readable treatises yet published on a subject which is too frequently dealt with in a somewhat formidable manner. No attempt is made to evade difficulties, since although starting with comparatively elementary work, the final chapters work up to the use of the quantum theory and statistical mechanics. As an instance of the human touch, the author allows himself in connexion with Callendar's equations for steam the use of the word "surprising" when conducting the reader along the interlocking paths of this fascinating piece of work. A little more of this spirit in the past might have shortened the twenty years which elapsed between its enunciation and acceptance.

Rather more than the first half of the book is taken up with the development of the usual theorems, including change of phase, equilibrium of systems, and the Nernst heat theorem. The kinetic theory first appears in a formal manner in Chapter vi, necessitating a reference forward from Chapter ii to some of its results. Though rarely adopted, a more logical procedure would seem to be to introduce it at an early stage: an additional advantage would be that it renders so much elementary work self-evident.

The applications which follow, to solutions, electrical phenomena including the magneto-caloric effect, radiation and specific heats according to the quantum theory, at times naturally make rather heavier reading. Numerous very recent references to original work are supplied for those who wish to go into each subject more deeply than is possible in the 300 pages of this book.

That this, a second edition, has b
is an indication of the usefulness of
value of which has been enhanced b

ENVIRONMENTAL CONDITIONS AND PHYSICAL CHARACTERS

Migration and Environment
A Study of the Physical Characteristics of the Japanese Immigrants to Hawaii and the Effects of Environment on their Descendants. By Prof. H. L. Shapiro, with the field assistance of Frederick S. Hulse. (Issued under the auspices of the University of Hawaii.) Pp. xi + 594. (London, New York and Toronto: Oxford University Press, 1939.) 32*s*. 6*d*. net.

EVER since 1912, when Boas published his studies upon the changes in bodily form of descendants of immigrants to the United States, speculations concerning the power of environmental conditions to affect the physical characters of man have been rife. At times these speculations have had but slender foundation in ascertained facts derived from proper anthropological investigation, and we have become accustomed to somewhat random statements concerning the differences in appearance between the migrants in their new environment and the parental stock in their homeland. It is obvious that the investigation of this problem is surrounded by pitfalls, and that no mere generalizations are of the least value in attempting its solution. Even when the problem is investigated by the standardized methods of anthropometry, there are still abundant sources of error that are difficult to eliminate but which will naturally invalidate the ultimate findings. It has been the first task of the reviewer to attempt the detection of any possible sources of error in the work under notice, and he freely owns that here he has failed.

The problem that Dr. Shapiro and his co-workers set for themselves was a threefold one. In the first place, they conducted an anthropometrical survey of the first generation of Japanese born in the Hawaiian Islands; in the second, of the Japanese who had come to the islands as migrants from Japan; and in the third, of the Japanese living in Japan representative of the stock from which the migrants came; this last class are termed by Dr. Shapiro 'sedentes'. We are therefore concerned with three classes: sedentes, immigrants and Hawaiian-born. It should first be made clear that all the measurements of more than three thousand individuals, whether made in Hawaii or in Japan, were recorded by the same observer. In the next place, it is important to note that the sedentes measured in Japan were inhabitants of the villages from which the immigrants were derived, and in a great many cases were actual relatives of the migrants. Of this large series of individuals there were recorded 43 measurements, 21 indexes and 41 observations.

From the enormous mass of data thus gathered together a simple and expected finding emerges, for it was found that the Hawaiian-born differed significantly from the migrant, mainly in a quantitative direction, by greater stature, increased length of limb and increased width and height of head among other things. So far, the finding seems to be the very natural one that change of total environment, often accompanied by change in social status and of occupation, has produced a quantitative change in the physical form of the Hawaiian-born Japanese. But the remarkable fact emerges that when the immigrants are in their turn compared with the sedentes, it is found that "in 18 out of 35 traits the immigrants diverged distinctively from the sedentes. In practically all the characters in which the immigrants deviate, no additional modification of noteworthy magnitude appeared among the Hawaiian-born".

Shapiro sums up this puzzling finding as follows:

> "These results lead to the conclusion that in both qualitative as well as in measurable characters the immigrants display significant departures from the means and percental distributions of the sedentes. The Hawaiian-born, however, fail to show any tendency to develop further modification in their qualitative characters, although in their quantitative traits they undergo considerable modifications."

How comes it that the men and women who left Japan as adults to migrate to Hawaii differ in physical characters so notably from the kin they left behind? It would naturally be suggested that some form of selection was exercised by the emigration officers in Japan or by the plantation owners in Hawaii; but this possibility seems clearly to be ruled out. It may be suggested that migrant groups are a naturally selected strain of the parent stock, but such a hypothesis is difficult to maintain. Whatever the underlying factor may happen to be, there is no doubt that this exhaustive piece of work has opened up a new field—a field concerning which the reviewer is in agreement with the author when he sums up his conclusions in saying, "We are thus reduced to the position of suspended judgment".

F. WOOD JONES.

STORAGE OF TROPICAL FRUITS

BY DR. C. W. WARDLAW,
IMPERIAL COLLEGE OF TROPICAL AGRICULTURE, TRINIDAD

WHEN work was begun at the Trinidad Low Temperature Research Station in 1928*, the immediate problem was to ascertain the keeping and carrying quality of the several banana varieties and hybrids which might be used as substitutes for the Gros Michel (the principal variety of commerce), then threatened by the epidemic spread of Panama disease. Within a few years, however, the very general use to which the Station could be put was recognized both by local agricultural administrations and by shipping companies operating in the Caribbean region, and by request work was in turn extended to tomatoes, limes, grapefruit, oranges, avocados, mangoes, papaws, pineapples, melongenes, cucurbits of various kinds, and to the assortment of vegetables that can be grown in the tropics. To some of these commodities a considerable amount of study has been devoted, and their general cold-storage requirements have now been ascertained with a sufficient degree of precision for practical purposes.

Success in transporting fruits and vegetables does not depend on refrigeration alone, and to a large extent it has fallen to those engaged on storage problems in the tropics to investigate, at least in part, related biological aspects such as the physiological behaviour of different varieties, questions of harvesting maturity, optimum conditions for harvesting, pre-storage and disinfectant treatments, the effect of different methods of wrapping and packing, post-storage treatments including ripening technique, and wastage problems in general. In the following notes some account is given of results obtained in Trinidad and of the varied botanical problems encountered in investigating the storage requirements of tropical fruits.

If not held at suitably low temperatures, the ripening of tropical fruits and the onset of wastage take place very rapidly. The practical problem, accordingly, is primarily one of arresting or retarding ripening without injuring the fruit. To do this satisfactorily, it is essential that rapid cooling to the required storage temperature should be undertaken as soon after harvesting as possible.

If an arbitrary and incomplete distinction may be drawn between 'cool' storage and 'cold' storage, it will be found that the greater number of tropical fruits require to be carried in 'cool' storage (for example, avocados, 45° F.; mangoes and tomatoes, 47·5° F.; grapefruit, oranges and limes, 45° to 50° F.; Gros Michel bananas, 53° F.

BANANAS

During the past decade, the maj
banana investigations has centred arou
for a variety to replace the Gros Miche
banana. This variety, which suffe

---

* Funds were provided by the former Empire Marketing Board.

disadvantage of being highly susceptible to Panama disease, is in all other respects almost uniquely suited to the conditions of bulk stowage and transport required in the extensive Caribbean industry; symmetry of bunch, disposition and size of fingers, uniformity of growth, toughness of skin, resistance to disease and ability to be carried at a temperature sufficiently low to effect a substantial control of fungal wastage, combine to make it not easily replaceable by other varieties. Investigations on the keeping quality of possible substitutes have chiefly served to accentuate the collective advantages possessed by the Gros Michel and the difficulties of obtaining a comparable assemblage in an immune variety. A note of optimism may be sounded regarding certain hybrids which have been obtained in Trinidad by crossing a wild, seeded variety (***Musa acuminata***) with the Gros Michel. These combine resistance to Panama disease and to Cercospora leaf disease with a very considerable assemblage of the desirable qualities of the Gros Michel. The first hybrid obtained, known as *I.C.*1, is open to criticism because it yields occasional seeds. The second, known as *I.C.*2, is seedless; it possesses many of the desirable Gros Michel characters and has good texture and flavour, but the individual fruits tend to be rather short.

Several interesting results have accrued from recent bulk storage trials. When the *I.C.*2 banana is grown under favourable conditions, it is capable of yielding good bunches, as judged by the appearance, symmetry and weight of individual fingers, 9-, 8- and 7-hand bunches, suitable for export, being represented among the collection of fruit obtained from different parts of Trinidad. While the symmetry of the bunch as a whole and the disposition and shape of individual fingers are admittedly not so good as in the Gros Michel, nevertheless the hybrid *I.C.*2 possesses qualities which would make it commercially important in the event of any major failure of the Gros Michel. Its present value as a source of food among the local peasantry should not be overlooked. In relation to current storage and ripening procedure for bananas, the optimum harvesting maturity lies between '¾-full' and 'heavy ¾-full', using Gros Michel standards of grading. 'Thin' grade fruit is difficult to ripen; 'heavy ¾-full' fruit, which behaves well during cold storage at 53° F., ripens with an excessive odour of pear drops. The Gros Michel transport temperature of 53° F., with rapid cooling to that temperature, is well suited to this hybrid.

It is generally agreed that the ideal hybrid banana of the future is likely to be one derived from the Gros Michel as female parent. Whether or not the *I.C.*2 eventually becomes acceptable as a commercial banana, any data which can be collected on its growth in the field and physiology in storage will contribute materially towards the central object of this work, that is, the maintenance of supplies of fruit of good quality.

During recent years the epidemic spread of Cercospora leaf disease in the Caribbean region has necessitated a renewal of storage trials with the Gros Michel banana. As a result of this disease many bunches undergo premature ripening while they are still attached to the plant. In storage trials it has been ascertained that the behaviour of fruit obtained from plantations which have been more or less severely infected by *Cercospora musæ* is abnormal in several respects; the pulp is of a slight to well-marked buff or pale ochraceous-salmon colour, fruit tends to ripen prematurely, to chill during the period of refrigerated transport, and to ripen with undesirable rapidity when removed to a higher temperature. Moreover, as a result of the extensive leaf destruction caused by *C. musæ*, bunches tend to grow slowly and to remain of small size; hence fruit may actually be considerably more mature than is indicated by its appearance, and departures from the normal storage behaviour for that grade may be anticipated.

LIMES

The storage of limes exemplifies in particular the importance of the humidity factor. In general, limes are more difficult to handle than lemons, being less cold resistant and, because of their small size, more subject to wastage through shrivelling; the avoidance of desiccation, indeed, is one of the major problems in handling this fruit, a loss in weight of 12–14 per cent being accompanied by severe shrivelling. As loss in weight under tropical conditions may amount to 1·5–2·0 per cent per day, the commercial storage life, as limited by the onset of shrivelling, may be seriously curtailed by undue delay whilst fruit is waiting to be graded and packed. Speedy handling, protecting of fruits by suitable wrappers, and rapid cooling to 45° F. are essential to the successful storage of this commodity.

The susceptibility of the West Indian lime to wither-tip disease has necessitated the breeding of new varieties. By crossing the Philippine lime with the West Indian variety a number of hybrids highly resistant to wither-tip have been obtained. One of these, known as the *T.*1 lime, is a fruit of good appearance, juice and oil-content and is now being cultivated and marketed on a not inconsiderable scale. A second hybrid, *T.*6, possesses less favourable commercial qualities, but has proved of interest when studied with the *T.*1 hybrid and the parental types. Under identical storage conditions, all four exhibit considerable differences in respect of loss in weight; weight for weight and grade for grade, the two hybrids are subject to more rapid desiccation than either of the parents. With regard to cold-resistance, the Philippine lime proved most resistant and the hybrid *T*.6 least; the hybrid *T*.1, on the other hand, is apparently more cold-resistant than the West Indian lime. Such variations are interesting in that they afford an indication of the rearrangement of physiological characters which may result from hybridization.

As with other kinds of citrus fruits, limes are very subject to the superficial blemishing known as oleocellosis which results from mechanical injury to turgid fruits. To avoid oleocellosis, fruits should not be picked too early in the morning or too soon after the fruits have been covered with dew or rain water.

GRAPEFRUITS

Because of the rapidly increasing importance of grapefruit as an orchard crop in the West Indies, an extensive programme of investigations has been carried out. Although data were available from experiments conducted in the United States, South Africa, and elsewhere, it was imperative, because of the relation between environment and keeping quality, to study Trinidad fruit entirely on its merits. In particular, attention has been directed to ascertaining the effect of time of harvesting, duration of the quailing or curing period prior to handling, the precise temperatures suitable for short or more prolonged periods in storage, the nature and incidence of chilling, the avoidance of excessive desiccation and the incidence and control of wastage. The behaviour of fruit derived from trees which has suffered from gummosis and root-rot also presented special problems of both practical and academic interest. Various commercial practices, for example, ethylene colouring, borax treatment, etc., which in some countries have now become standardized, when applied to Trinidad grapefruit have yielded results other than those expected. Thus when fruit is treated with borax solution before crating, as a means of controlling blue and green moulds—which, as a fact, are of minor importance in Trinidad—the effect of the fungicide is to promote the activities of the fungus *Colletortichum glœosporiodes*, which is already present within the tissues as latent infections, so that severe wastage may result. A similar effect is produced by the use of iodized wraps. Striking variations in the keeping quality, susceptibility to chilling and to fungal disease in fruit from different localities in Trinidad have also become apparent in studies conducted over a number of years.

AVOCADOS

The avocado, which is native to Central America, is represented in the West Indies by a very considerable range of types. The majority of trees are of seedling origin and so far only a few have been selected, named and used in the propagation of standard types. The influence of environment and genetical constitution on physiological behaviour during storage is well shown by the avocado, such information as was available from investigations undertaken in America being inapplicable to fruit grown under Trinidad conditions.

Cultivated avocados are generally referred to three horticultural races, the Mexican, the Guatemalan and the West Indian, useful types being fixed- and propagated by budding and grafting. Seedling avocados of the third group as grown under West Indian conditions are characterized by a low fat content, great variation in all fruiting characters, and by their comparative intolerance of cold-storage conditions (most varieties show chilling injury when held at temperatures below 50° F. (10° C.)). A distinctive feature of the avocado is its high fat content. It has been ascertained that fruit grown in Trinidad, and presumably elsewhere under moist tropical conditions, has a considerably lower oil content than that produced in Florida and California. In Trinidad, this low oil content, which is apparently largely determined by environmental factors, is characteristic of introduced as well as of local varieties.

Experimental observations indicate that the striking variability in fruiting characters of West Indian avocados is closely paralleled by the range in behaviour exhibited by fruits when subjected to refrigerated or gas storage or to a combination of both. In the avocado, maturation slowly continues even at relatively low temperatures, so that fruits ultimately become ripe. In varieties not sufficiently cold resistant, the metabolic trend is, however, abnormal, and chill effects in due course become apparent in a darkening of the vascular strands and storage parenchyma, the initiation of such changes being closely associated with the onset of ripening. As only a small number of varieties combine the requisite commercial qualities with adequate cold resistance, the practical problem is essentially one of selection.

MANGOES

In investigating the storage of mangoes, it has been necessary not only to select from the very considerable number of named and seedling varieties available for study, but also to consider such diverse aspects as criteria of harvesting maturity in the several varieties, and the effect of season and environment on keeping quality and liability to wastage. A finding of interest to horticulturists is the very marked effect that environment may exercise on the productivity and keeping quality of different varieties. Thus, whereas the Julie variety crops well and gives a fairly good storage life when grown under the moist conditions that prevail in Trinidad, the Peter's variety is of uncertain productivity and is very susceptible to fungal rotting; on the other hand, the Peter's (Pairi or Bombay) variety, as grown under the dry conditions found in certain areas in Jamaica, yields export fruit of excellent quality.

Like many other tropical fruits, mangoes are readily subject to low-temperature injury. Chilling may be manifested in several ways, including the production of definite skin blemishes, failure to develop normal colour on ripening, failure to ripen on removal from cold storage, and a notable decline in resistance to the inroads of pathogens. Susceptibility to chilling varies with variety, maturity at harvesting and season. Trinidad experience indicates that mango varieties in general are subject to chilling injury if exposed to temperatures below 48°–50° F., superficial blemishing being accentuated by partial desiccation.

The wastage problem in mango storage is serious. Apart from damage due to wound parasites (which is inconsiderable in carefully-handled fruit) the majority of fruits, though apparently free from disease, nevertheless carry latent infections of several important pathogens. Wastage attributable to such latent infections is greatly accentuated by chilling, slow ripening and tardy distribution of ripe fruit. The high incidence of field infections directs attention to the need for careful consideration of orchard sanitation, and it is evident that questions of spacing, pruning, spraying and upkeep generally should be made subjects of special study.

PAPAWS

The papaw (*Carica papaya*) may be cited as an example of a tropical crop where little progress can be made in the matter of commercial cold storage until standardized supplies of fruit are made available as a result of horticultural research. The papaw is well known as the source of the digestive substance papain, obtained by coagulating the latex exuded from green fruits on wounding. During recent years some attention has been paid to this fruit as a possible export crop notably in South Africa and the West Indies. An attempt has also been made to extend papaw cultivation in California and to breed varieties adapted to prolonged storage or transport. From the information available on the production and cold-storage behaviour of this fruit, it may be predicted that the organization and standardization of an export industry will be attended with serious difficulties.

The papaw shows great variety in its fruiting characters, some types producing small spherical fruits no larger than an orange, while others have elongated fruits as large as a watermelon and weighing up to 25 lb. In working towards an export trade, standardized production is a first essential; the basic problem is, therefore, to select and perpetuate good types from material which is notoriously variable. Again, as most varieties are diœcious, the liability to a low standard of production is accentuated by the number of male plants present in a sowing.

Storage trials carried out in Trinidad have shown that relatively immature papaws will not ripen after cold storage, and further, that most of the varieties tested show evidence of chilling if held at temperatures lower than 55°–60° F.

TOMATOES

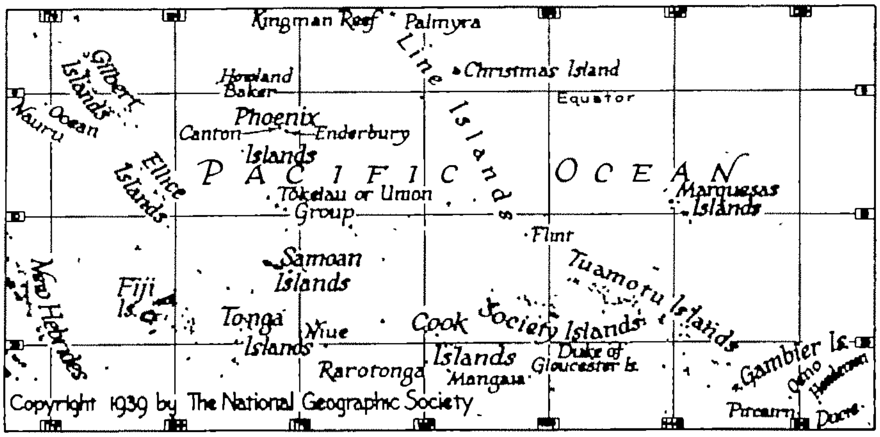
Tropically-grown tomatoes may be mentioned as illustrating the unexpected in storage investigations. Thus it has been ascertained that fruits of several varieties grown under Trinidad conditions have yielded storage records which compare very favourably with those obtained elsewhere. When picked full-grown but green, Trinidad fruit can be kept in cold storage at 40°–47° F. for twenty to thirty days, and on removal to a higher temperature remains in good condition for a further eight to ten days. These results have been confirmed over a number of years and are in marked contrast to the rapid degeneration recorded in comparable storage trials with fruit grown outside the tropics. In view of the disparity between Trinidad findings and previous English results, storage trials were undertaken at the Low Temperature Research Station, Cambridge, in which supplies of glasshouse fruit grown during summer and autumn respectively were used; the summer fruit gave results comparable to those obtained in Trinidad; the autumn fruit, on the other hand, was characterized by the poorer keeping quality already mentioned. As to why summer-grown fruit or that obtained under tropical conditions should be more tolerant of low temperatures is not understood.

During recent years the terms of the grant from the Colonial Development Fund by which this Station is maintained include a concentration on fundamental research with special reference to the banana.

UNITED STATES GEOPHYSICAL EXPEDITION TO THE PACIFIC OCEAN

BY PROF. S. CHAPMAN, F.R.S.

A NOTABLE expedition has been arranged by the National Geographic Society of America and the University of Virginia, with the co-operation of the United States Coast Guard, to undertake varied geophysical investigations in the Central and South Pacific Ocean. The expedition will start in September next, and its work will extend over a whole year. It will be transported by a 2,000-ton steel Coast Guard cutter, fitted with the latest type of sonic depth-finding apparatus, and carrying a two-seater scout observation seaplane which will be used in making aerial photographs and island maps. While the scientific work is proceeding, the Coast Guard will make a survey of present and future needs for navigational and radio aids to marine and air commerce.



Copyright 1939 by The National Geographic Society

The expedition will range over an area of 4½ million square miles, south of the Hawaiian Islands, east of Australia and New Guinea and north-east of New Zealand; most of its work will be done on the many islands scattered over this area. These islands are all owned or controlled by the United States of America, France, and Great Britain or the British Dominions; westernmost of those to be studied is Nauru, practically on the equator, about 800 miles north-east of Australia. Easternmost is Ducie Island, nearly in the longitude of San Francisco, almost on the tropic of Capricorn. The northern and southern limits of the area studied will be Kingman Reef (500 miles south of Honolulu) and Pitcairn Island. The expedition will sail from San Francisco, first visiting Canton Island, now under joint American and British control. During its twelve months in the field, the ship will put in at intervals at Honolulu and Auckland, New Zealand, for supplies and mail. From time to time the expedition will send out radio broadcasts describing its progress.

The expedition will set up major bases on twenty or more islands, and from each major base will visit from ten to fifty other islands. All the islands except those of the Fiji and Tonga groups (which are of the 'continental' type, with a foundation of very old granite) are of the 'pure Pacific' type, either of recent volcanic origin, or of coral resting on recent underwater volcanic outpourings.

Gravity determinations and magnetic observations, together with careful observations of latitude and longitude, will be made on the islands visited, and at the same time the geology of the islands will be studied: the region is virgin ground for the gravity survey, and of course magnetic observations everywhere need to be repeated every decade or so in order to keep up to date our knowledge of the earth's changing field. Artificial seismic waves will be set up by explosions on the ocean bed to indicate the types and depths of rock below; mud 'cores' will also be obtained, showing the composition, for a depth of several feet, of the top layer of the ocean floor. Observations on marine biology will be made, and radio engineers will accompany the expedition in order to investigate radio phenomena.

The expedition is thus one of the most important and extensive scientific exploration surveys undertaken by any country for many years: in several respects its programme coincides with that which was recently arranged, for work over a much more limited area (on or near the edge of the continental shelf off the British coasts), by the Royal Society with the co-operation of H.M. Navy—though the completion of that survey was prevented by the political crisis of last September. It is greatly to be hoped that the plans for the proposed United States expedition may be carried through fully and successfully.

OBITUARIES

Mr. H. Havelock Ellis

BY the death on July 8 of Henry Havelock Ellis, both science and literature have sustained a heavy loss. Havelock Ellis was born at Croydon eighty years ago. At sixteen years of age, owing to ill-health, he was sent to Australia, and later became an assistant schoolmaster in a suburb of Sydney. During a lonely adolescence he was greatly troubled by moral and spiritual difficulties, and decided to devote his life to systematic inquiries that should make clear to himself and to others the real nature of the problems of sex. With this in view he returned to London, and trained as a general practitioner at St. Thomas's Hospital.

After a few months in general practice, literary and scientific activities began to absorb all Havelock Ellis's time. He became editor of the "Contemporary Scientific Series" and co-editor of the "Mermaid Series" of old dramatists; and was soon widely known as a critic and essayist, and later as a popular philosopher and an interpreter of the national genius of France and Spain. His books on "The World of Dreams", "Man and Woman", "The Criminal", "A Study of British Genius", revealed his strong psychological interests and his gift for impartially collecting scientific observations and expounding scientific facts in a lucid and impartial way.

In a long list of publications, the most important work written by Havelock Ellis was that entitled "Studies in the Psychology of Sex". There is no need to repeat the oft-told story of the prosecution of its publisher, and the founding of a defence committee which included George Moore, William Sharp and Bernard Shaw. In spite of judicial condemnation, the volumes might have been seen on the shelves of most British psychologists at the beginning of this century; and his influence undoubtedly paved the way for the sympathetic interest aroused by Freud's more startling doctrines later on. Freud himself, indeed, has more than once acknowledged the value of Havelock Ellis's pioneer work.

Unlike Freud, Ellis was more interested in collecting data than in constructing theories. The results of psychological tests were duly reported in his pages whenever they were obtainable; but since experimental work was only in its infancy when he wrote, his books will remain a collection of suggestive observations rather than of experimentally verified facts. His views on crime, on genius, on the mental differences between the sexes, though still freely quoted, can no longer be regarded as representing the results of the latest researches. Nevertheless, his lucid and delightful style, and the charm of personality that shines through it, will keep his psychological writings alive and influential when the publications of the academic psychologists of his day lie dead and forgotten.

Dr. Henry Correvon

THOUGH better known as a horticulturist than as a botanist, Henry Correvon made considerable contributions by his numerous publications to botanical science. His death in his eighty-fifth year on May 11 leaves a notable gap among the devotees of alpine plants, whom he has done so much to encourage and assist by his own enthusiastic labours.

Born at Iverdon in 1854, Correvon was educated in this little Swiss town, and, losing his father at an early age, was sent to learn horticultural practice first to Geneva, then to Zurich, Frankfort, Erfurt and finally to the Jardin des Plantes in Paris, where he received botanical as well as horticultural training. Thus well equipped, he returned to Iverdon to take charge of the horticultural establishment founded by his grandfather, which had suffered greatly from the neglect of the tenant who had carried on the undertaking. Capable and energetic, Correvon commenced to work up this family heritage, but, alas, only to see most of his improvements totally destroyed by a devastating cyclone in July 1877. The low-growing alpine plants alone survived the ravages of the storm. He transferred his energies to Geneva, where he established a nursery for alpine plants, in the cultivation of which he was so successful that he ultimately purchased in 1902 a large vineyard at Chêne-Bourg high above Geneva. Here he created the wonderful garden "La Floraire" known to all cultivators of alpine gardens. To it he had transported limestone rocks from the Salève and the Jura and granite blocks from the Alps so as to have suitable surroundings for his pet plants.

Correvon's interest in these was not limited to those in his own garden. He was one of the originators of "La Linnea", the alpine garden at Bourg St. Pierre, now under the management of the University of Geneva. He was also concerned in the management of the alpine garden on the Rochers de Naye above Montreux and for a time with that above Saint-Cergue. His love for these, and other efforts for the preservation of the mountain plants, made him a prime mover in the formation of the Swiss Nature Protection Society.

Alphonse de Candolle persuaded Correvon to learn English, and for some years he acted as a correspondent of the *Garden*. In 1886 he visited England and wrote enthusiastically about some of the gardens he saw, and spoke with admiration particularly of the cultivation of the terrestrial orchids by various British horticulturists. This group of plants was particularly dear to him and led to his publication of a little book in 1893 on "Les Orchidées rustiques", followed in 1899 by his "Album des Orchidées", of which a second edition has appeared. His publications were, however, not limited to orchids. They included books on trees, ferns, flowers of fields and forests, water and marsh plants. His book on "Rock Garden and Alpine Plants", translated from the French edition, was published in New York. His "Alpine Flora", with its wonderfully artistic representations of the plants described, appeared in an English translation in London.

Correvon was an indefatigable worker and an excellent lecturer. Ten years ago, at the age of seventy-three years, he undertook a visit to the United States, where he gave some forty lectures and addresses in English to promote the interest in alpine gardens. He was an honorary member and correspondent of many horticultural societies and was awarded an honorary doctorate of the University of Geneva in 1931.

He retained his full powers of body and mind until the end, and his beloved garden at Chêne-Bourg is assured of its continuity in the hands of his son and his grandson, both trained gardeners and possessing Henry Correvon's devotion to alpine plants.

Sir Frederick Hobday, C.M.G.

THE veterinary profession has lost a pioneer of
bility with the passing of Sir Frederick Thomas
eorge Hobday at the age of sixty-nine years on
une 24.

Hobday graduated at the Royal Veterinary College
1892. His early contributions to veterinary science
ere on the applied side. He was responsible for the
iore general use of anaesthesia in veterinary surgery,
nd decreased the hazard of volatile narcosis by
eans of inhalers, which he designed to control the
pth of anaesthesia. In addition he developed
ethods of abdominal surgery in large animals, and
ccessfully applied the Williams technique for the
lief of roaring in horses.

Sir Frederick's real scientific achievements cannot
judged by his publications, but rather by his
tive and successful efforts in creating research
ilities at the Royal Veterinary College, and in
nging the medical and veterinary branches of
dicine into more intimate contact by the formation
the Section of Comparative Medicine in the Royal
iety of Medicine. He was the first veterinary
sident of this section (1924–26).

n 1927, Sir Frederick was made principal of the
yal Veterinary College. He took over a college
buildings of which were in danger of collapse
the financial position of which could not have
n worse. His enthusiasm enabled him to raise
voluntary subscription the sum of £135,000. This,
ther with a Treasury grant of £150,000, made it
ible for him to realize his ambition of rebuilding
College. The new main block, housing the long-
led research and teaching facilities, was formally
ed in 1937 by the King and Queen.

his ten years of strenuous endeavour drained
day's strength, and the unexpected termination of
rincipalship in 1936 came as a heavy blow both
n and to his many friends, though formal resigna-
was delayed until the opening ceremony. His
efforts, however, had received recognition by
conferment of knighthood in 1933. He was hono
Veterinary Surgeon to Queen Alexandra,
George V, King Edward VIII and King George

The Royal Veterinary College in London st
as a monument which will always be associated
his name, and those working there will be remi
that it was due to his unremitting energy that
excellent facilities are available.

J. YULE BOGU

Dr. W. H. Neale

DR. WILLIAM HENRY NEALE died on June 1
his eighty-third year. He was born in Batavia, w
his father, Dr. Richard Neale, was then in prac
He came to England as a boy and attended a pri
school at Hampstead. He studied medicine at Ki
College and University College, London, and
the degree of M.B. in 1879, proceeding to M.D. in 1

In 1880 Dr. Neale joined Mr. B. Leigh Smit
surgeon and naturalist on a sporting and explo
voyage in the steam yacht *Eira* to the then alr
unknown coast of Franz Josef Land, where discove
of considerable geographical importance were m
In 1881 Dr. Neale returned with Mr. Leigh S
in the *Eira* on a more ambitious summer expedi
to the same region, where the yacht was caugh
the ice-floes and sunk close to Cape Flora.

The disaster was so sudden that very little c
be saved from the wreck and the only hope of re
was in the power of the ship's company to
themselves. A hut large enough to house the twe
five men was built and Mr. Leigh Smith's skill
hunter secured an adequate supply of walrus
bear meat. Dr. Neale had charge of the rationin
the food so as to preserve the health of the
such tinned provisions as had been saved being
for the homeward boat voyage. He was trouble
the prospect of an outbreak of scurvy in the abs
of lime-juice, in which the British sailor
learned to trust as the only preventive. He fo
however, that the fresh meat diet was in fact
best possible antiscorbutic, and on his return he d
with the etiology of scurvy in several communicat
to the medical press, and he must be viewed as
of the first to recognize the value of fresh mea
a preventive.

The winter of 1881–82 was passed safely tho
the temperature sank to − 40°. When the
began to break up at the end of June a start
made to the south in four small open boats. T
were hardships in plenty and a baffling journe
more than 500 miles to be made through the shif
leads of the icefloes and in the open sea. After
weeks, the relief ship *Hope* was met on the c
of Novaya Zemlya, and the whole party were stil
sound health in spite of the trying experience.

Dr. Neale studied the natural history of the C
Flora region and described his collections in
Proceedings of the Zoological Society. He becan
valued fellow of the Royal Geographical Society
frequently spoke after polar papers.

For more than half a century, Dr. Neale lived as a general practitioner in the St. John's Wood district, endearing himself to an increasing circle of friends by his skill, devotion to duty and trust-begetting kindness.

HUGH ROBERT MILL.

WE regret to announce the following deaths:

Prof. H. H. Barnum, head of the Department of Mathematics in Robert College, Istanbul, aged sixty-one years.

Dr. W. A. Potts, a pioneer in the psychology of crime, on July 23, aged seventy-three years.

Prof. E. R. A. Seligman, McVickar professor of political economy and finance in Columbia University during 1904–31 and editor of the "Encyclopædia of Social Sciences", aged seventy-eight years.

Mr. J. M. Wood, formerly engineer of the New River Company and of the northern district of the Metropolitan Water Board, on July 21, aged eighty years.

Prof. Archibald Young, regius professor of surgery in the University of Glasgow, on July 23, aged sixty-five years.

NEWS AND VIEWS

Dr. Wilson Smith

DR. WILSON SMITH, who has just been appointed to the chair of bacteriology in the University of Sheffield, graduated in medicine at the University of Manchester in 1923, after War service in France and Belgium with a field ambulance during 1916–19. He obtained the diploma in bacteriology at Manchester in 1927 and was granted the M.D. degree in 1929. For the last ten years he has been a member of the scientific staff of the Medical Research Council and during this period he has made many valuable contributions to knowledge on bacteriological problems—such as the standardization and assay of pneumococcus antisera—and also on various virus diseases. Perhaps the most important of these latter contributions are the facts regarding the virus of epidemic influenza. As a member of a team, he was one of the discoverers of this virus and he helped to lay down criteria for its recognition; he did much of the pioneer work which has led to a renewed and intensive investigation of influenza throughout the world. Since 1934 he has been one of the editors of the *British Journal of Experimental Pathology*.

Mr. Hugh Main

THE council of the British Empire Naturalists' Association has elected Mr. Hugh Main as new national president in succession to Mr. Douglas English, who recently retired owing to ill-health. The presidency of the Association is not an annual affair and the choice of Mr. Hugh Main will meet with wide acclamation, for he is well known for his interest in nature photography and his insect studies. He spends much time in his private photographic studio at Woodford Wells in Essex, or in collecting insect specimens. He has long been a vice-president of the Association, and when the new Epping Forest Branch of the Association was formed, Mr. Main was elected its first president. He has made conspicuous contributions to nature photography and he has also been an active man in the field as well as on the lecture platform. He has also made some noteworthy experiments with his insectarium. Mr. Main has long been a keen and enthusiastic worker for the Association and has done much in various ways to promote its welfare. He is the Association's referee for beetles. The British Empire Naturalists Association now has twenty-four local branches each with separate meetings and officers, and thirty-five other natural history societies are affiliated to it.

Public Health and the Supply of Medicaments

THE address of Mr. J. Rutherford Hill, as chairman of the Pharmaceutical Conference, which met at Birmingham on July 17–21, was entitled "Public Health in relation to the Recognition, Definition, Standardisation and Controlled Supply of Medicaments", and he makes recommendations under all these heads. Lists of recognized drugs are supplied by the national pharmacopœias of many countries; it is hoped that these will eventually be replaced by an international pharmacopœia, but this would not solve the whole problem. Medicine is advancing rapidly and pharmacopœias soon get out of date. Some authority in Great Britain should publish a list, like the American list of New and Non-Official Remedies, which would be kept constantly up to date. The British Medical Association and the Pharmaceutical Society of Great Britain have recently been forced by considerations of cost to abandon the proposal to publish such a list jointly. The Government should undertake this important public service. Proper regulations for the definition of medicines would make it impossible for the manufacturers to confuse the public, and fill up the shelves in pharmacies, by selling the same simple chemical substance under a dozen synonyms. Mr. Hill also recommends that the present arrangements for the standardization of medicines should be extended, and that their retail sale should be confined to pharmacists. This would not mean a monopoly for one class of the community, but only that those firms which sell medicines should be compelled to employ salesmen who have been properly trained.

Marking of Patent Medicines

WHEN the question of withdrawing Medicine Stamp Duties was debated recently in the House of Commons, it was clear that there was a general feeling that proprietary medicines should not be freed from all restrictions, but should be subjected to effective control. Some of them are fraudulent, their advertisements encourage healthy people to think they are ill, and unhealthy people to postpone taking medical advice until it is too late, and some of them are poisons. The recent passing of effective legislation in the United States was largely due to the fact that seventy-three people were killed by an elixir containing diethylene glycol, just at the time when the matter was being debated in Congress. It would be unfortunate if another such accident were to occur in Great Britain before effective measures were introduced. Reforms of various kinds are being widely discussed. Prof. A. J. Clark, in a little tract published last year under the title "Patent Medicines" said: "The clearest line for the Government to take would be to say that it did not wish to tax any remedy that was beneficial to the health of the people, and wished to suppress all those that were useless and harmful." This would imply regulations such as those now enacted in the United States, where new remedies can only be sold when they have been officially approved. Lord Horder, in his speech in the House of Lords, stressed the harm that is done by misleading advertisements and recommended that measures for the control of quack medicines should form part of the campaign for national fitness.

Organization for War Emergency

EXTENSIVE preparations are in progress to meet a possible war emergency, not only in regard to defence, but also in other directions. On the medical side, the Ministry of Health has issued a "Statement Relating to the Emergency Hospital Organisation, First Aid Posts and Ambulances" (London: H.M. Stationery Office. 4*d.* net). This sets out, in the first place, emergency hospital requirements and organization, schemes for dealing with casualties and ambulance services. A summary is then given of supplies that are being provided. These include 200,000 beds with mattresses, 320,000 blankets, with a corresponding sufficiency of sheets, pillows, pillowslips and towels, and 226,000 stretchers with 400,000 coloured blankets. In addition, drugs and dressings to the value of £237,000 are on order, as well as surgical equipment and appliances sufficient for 75,000 casualty beds. On the food side, the Government has advised all who can to lay in a week's store of emergency food. In order to translate the Government's advice into practical terms, the British Medical Association has issued a booklet, which should be in the hands of every householder ("How to Stock your A.R.P. Larder". 2*d.*). This gives advice on the stores that should be purchased in order to provide a week's food supply for a family of five. The approximate cost of the articles suggested is given, together with hints for storage and use, a few sample recipes for one dinner, and the food values of the rations mentioned.

Nutrition and the Public Health

THE proceedings of one of the most useful conferences of recent years—the National Conference on the Wider Aspects of Nutrition organized by the British Medical Association and held in London at the end of April—have recently been published under the title "Nutrition and the Public Health" (B.M.A. House, W.C.1. Pp. 150. 2*s.* 6*d.* post paid). This conference, a report of which appeared in NATURE of May 6, p. 745, brought together representatives of medicine, agriculture, industry, administration and education to discuss in a comprehensive way the relation of human nutrition to the national welfare. It urged upon the Government the formulation of a long-term food policy in which the requirements of health, agriculture and industry should be considered in mutual relation, and recommended the inauguration of an educational campaign to make such a policy effective. The Conference ranged over a wide field, but as the published proceedings clearly indicate, there was the thread of the urgent need for an active, informed Government policy, which should take as its main objective the abolition of malnutrition, running through every discussion. The common benefit to the health of the individual citizen, to the prosperity of the home farmer (who would be largely responsible for the perishable 'protective' foods so essential to such a scheme) and to the efficiency of industry of such a policy forms the triple basis of what is undoubtedly one of the clearest and most influential appeals yet made for the early application of modern nutritional knowledge to national well-being.

Teachers on Modern Education

THE addresses delivered at sectional meetings arranged in connexion with the recent annual conference at Llandudno of the National Union of Teachers (Hamilton House, Mabledon Place, London, W.C.1) have been issued as a bound pamphlet. They include one by Mr. Kenneth M. Lindsay on the development of our educational system, in which he suggests that a commission is required on the whole financial relation between central and local government if the implications of the Spens Report are to be carried out. He also stresses the need for developing technical education, including the provision of improved premises and closer co-operation between technical education and industry and commerce. Emphasizing the importance of adult education, he pointed out the need for an effective survey of this field. Dr. C. F. Strong's address on the teaching of citizenship in central schools refers to the importance of including the civic aspects of science in a science syllabus, and urges the importance of history as laying the foundation for the teaching of citizenship and dispassionate thinking about political questions. Mr. E. R. J. Hussey's paper on aspects of education considered as a preparation for life in the modern world also emphasizes the importance of science, especially biology, from this point of view as well as the importance of character training and the formulation of ideals and a sense of values. Dr. G. H.

Green's address on the cinema and handicraft training directs attention to the need for investigation in the technique of using the film in schools.

The Hebrew University, Jerusalem

The Hebrew University, on the heights of Scopus in Jerusalem, is developing fast and well. Begun in 1923 with a Chemistry Research Institute, it is to-day a centre of research and instruction, with faculties in the main branches of learning, an academic staff, including research workers, of 125, and a students roll, under- and post-graduate, of 850. More than 30 per cent are women. Hebrew is the language of instruction. In some Departments are men pre-eminent in their own academic field. Prof. Bernhard Zondek, professor of gynæcology, is in charge of the Hormone Research Laboratory which is now attached to the new Medical Centre opened in May of this year. Prof. S. Adler, head of the Microbiology Department, has already achieved an international reputation for his pioneer work on tropical diseases transmitted by parasites, and has undertaken several expeditions on behalf of the Royal Society. Prof. A. E. Fraenkel, formerly of the Universities of Marburg and Kiel, is one of the professors in the Mathematics Department, with mathematical philosophy and foundations of theory of sets and of analysis as his special field. The Archæological Department, under Prof. L. A. Mayer, works in close association with the Department of Classics.

Two new faculties have been added this year, a medical faculty—it was formerly only a pre-faculty—and agriculture. The new professor of agriculture is Prof. E. Volcani, director of the Experimental Research Station at Rehovoth. The Hebrew University has played its part in enabling academic refugees to continue their work. Already nearly fifty exiled German scholars have been found positions at the University. These include Prof. H. Torczyner, the interpreter of the Lakhish Letters, Prof. J. Guttman, the authority on Jewish medieval philosophy, Prof. Martin Buber, the social philosopher, Prof. B. Zondek, the gynæcologist, Prof. Halberstadt, the radiologist, and the brothers Adelbert and Ladislaus Farkas, who are directing the Department of Physical Chemistry. The work already done gives promise that perhaps in the not-distant future Jerusalem will once again become the centre of learning in the Near and Middle East.

University and Professional Standards in the U.S.A.

The formulation of standards in respect of such matters as entrance and graduation requirements, staff, equipment and financial resources, and the accrediting of educational institutions with reference to them, are undertaken in the United States by voluntary national and regional associations and by State universities and departments of education. Lists of accredited institutions are published from time to time and the situation is reviewed by the United States Office of Education once in every four years. Bulletin No. 16, "Accredited Higher Institutions, 1938" (Supt. of Documents, Washington, D.C., pp. 212; 20 cents) brings together the latest available lists and standards of both voluntary and State accrediting agencies. The most noteworthy development of the past few years is the drawing up by the Engineers' Council for Professional Development of a statement of principles (reproduced in the Bulletin) for accrediting engineering curricula with the object of improving the status of the engineering profession. Other national associations have published lists of accredited professional and technical schools of law, theology, medicine, pharmacy, osteopathy, optometry, music, architecture, business, librarianship, journalism, forestry, social work and teaching. A National League of Nursing Education is conducting a survey with the intention of issuing a list of accredited schools on its completion. Of the university accrediting agencies, the chief and most exclusive is the Association of American Universities, which regards as the principal ground for the inclusion of a college in its approved list, evidence of success "in stimulating scholarly interest in its students and in preparing them for more advanced scholarly endeavour".

The Carnegie United Kingdom Trust

Twenty-five years have elapsed since Mr. Carnegie founded, with a capital of ten million dollars, his Trust "for the improvement of the well-being of the masses of the people of Great Britain and Ireland", and the Trustees preface their report for the year 1938 with a brief retrospect, in the course of which the allocation of their revenues since the Trust's foundation is summarized under the headings: libraries £1,393,000, physical welfare and playing fields and play centres £471,300, rural development and social service (including land settlement) £541,800, organs and other musical and dramatic activities £330,500, adult education £66,600, other activities £339,500. In pursuance of Mr. Carnegie's injunction to remember "that new needs are constantly arising as the masses advance" the Trustees aim at fulfilling the role of a pioneer body, financing no enterprise for more than a limited period, during which its sponsors are expected to contrive means for maintaining it, should its continuance appear expedient, without further recourse to the Trust. This principle plays a decisive part in the framing of the programmes of constructive experimental work which are drawn up by the Trustees once in five years and which pre-determine the bulk of the expenditure of each year's budget.

The current programme covers activities classified as: (*a*) cultural and æsthetic developments, including libraries, museums, music and drama, adult education; (*b*) social services, in many of which the National Council of Social Service collaborates, including village halls, community councils, shows and exhibitions, university settlements, village colleges, women's institutes, Zoological Society's films, national parks, youth services, etc.; and (*c*) land settlement. One of the notable events of the year was the publication of a report in furtherance of the policy inaugurated ten years ago for developing the educational function of museums of the British

Isles. The report, based on a two years survey by Mr. S. F. Markham, is accompanied by a short non-technical pamphlet, "Museums and the Public" for the use of museum committees.

Mycenean Athens

The discovery at Athens of a chamber-tomb of Mycenean age, which presumably had served for a royal burial, corroborates tradition, but at the same time necessitates a new orientation in assessing the importance of the settlement of Attica in early pre-classical times. The chamber was brought to light in the course of the present—the ninth—season of excavation on the Acropolis by the American School of Classical Studies. In a preliminary account of the discovery (*Illustrated London News*, July 22), Prof. T. L. Shear of Princeton University, field-director of the excavation, states that the tomb is situated in shallow accumulations of deposit on the northern slope of the Acropolis. It consists of a rectangular chamber, filled with splintered rock and approached by a dromos, or passage, some 45 ft. in length, but which originally may have been longer, as the outer end is cut by the Roman wall. The earth-filling of this passage contained a number of Mycenean pot-herds. Both passage and burial chamber had been cut from the rock; and the entrance to the chamber rom the passage is through a rock-cut doorway. This doorway was closed by carefully packed stones, which clearly had not been disturbed since they were placed n position.

Inside the chamber on one of the rock-cut enches, which run along each side, were six vases nd a cylindrical ivory box in their original position. he vases had been crushed by the collapse of the oof, but the ivory box, which is described as "a asterpiece of artistic design and of technical execuon", was intact. East of the doorway were two large ses standing on the floor by a copper ladle. The ave was cut in the rock to a depth of four feet. had been covered by a stone slab; but this had en removed, and lay diagonally by the grave. either bones nor offerings were found in the grave, though there was one small disk of gold in the earth d stones which filled the grave. On the floor beside e slab lay a group of small toilet articles—a bronze rror, a small ivory box, and ivory pins; and th of the grave, also on the floor, were three piles gold ornaments. The pottery is of a single period d is characteristically Mycenean in form and coration. Exact parallels can be found in Mycenean ttery from the Argive Heraeum and elsewhere longing to the third Late Helladic period of the t half of the fourteenth century B.C. The state in ich the tomb was found and the character of the rings lead Prof. Shear to the conclusion that this the burial place of a lady, probably belonging to royal house of Erechtheus, the legendary king of hens, whose body was removed when the roof of chamber collapsed; while the wealth of the rings—overlooked when the body was removed—es rise to a completely different conception of the gdom of Erechtheus in the fourteenth century B.C. from that conveyed by the fragmentary remains the walls of his palace, which have been discove on the Acropolis, and the unimportant part pla by Athens in the Trojan War five generations la as recorded in the Homeric poems.

Industry and Agriculture in Belgium

In a pamphlet on the National Foundation Scientific Research and Industry, the contribution this body to industry and agriculture in Belgium d ing the last ten years is reviewed by P. Beghin, secretary of the Foundation (Pp. ix + 408. Bruxell Fonds National de la Recherche scientifique). Si the Foundation gave its first grant in July 1928, persons have received grants, 75 of whom are s receiving them, while 35 fresh grants are made ea year. In subsidies of all kinds, 25,000,000 francs been distributed amongst 1,350 research worke The annual budget of the Department of Industr Science of the Foundation is limited to 1,000, francs. Taken by industries, the distribution research effort is concentrated mainly in agricult and horticulture (1,532,460 francs), metallur (1,299,000 francs), electrical engineering (1,209,4 francs), out of a total of 7,166,810 francs, chemist coming next with 730,750 francs and civil engineeri with 630,100 francs. The report includes more or l detailed accounts of work in progress in metallur welding, the thermodynamics of heavy-oil moto electrical apparatus, including incandescent elect lamps, radio reception, civil engineering, includi the action of wind on buildings, chemistry, includi synthetic lubricating oils, copal gum, synthe resins for the electrical industry, vulcanization rubber, the charcoal industry, glass industry, ceme industry, optical industry, as well as in agricultu including the disinfection of plants and the cultivati of the beetroot, the brewing industry and the tanni of leather.

British Museum (Natural History): Recent Acquisitio

An interesting acquisition in the Department Zoology is a series of the golden mole, *Eremital granti*, presented by Captain G. C. Shortridge of t Kaffrarian Museum, King William's Town, Sou Africa. The gift comprises seventeen skins and sku of this insectivore, and forms a valuable addition the study collections. Mr. F. N. Ashcroft has p sented to the Department of Mineralogy a furt selection of well-crystallized minerals from for seven carefully recorded localities in Switzerla The Ashcroft collection of Swiss minerals is unrivall in the excellence of the specimens and the care w which the localities have been recorded. This lat gift brings the number of specimens added to t Museum's collection from this source in the last t years to a total of 3,654. Another interesting g comes from the McGregor Museum, Kimberl through Miss M. Wilman, the curator, and consi of three specimens of the doubly refracting Icela spar found in Cape Province, South Africa. collection comprising about 4,900 gatherings plants has been brought back from South Amer by Mr. A. H. G. Alston, assistant keeper in t

Department of Botany. Of these about 1,900 are vascular cryptogams. The collection is rich in duplicates and there are about 20,000 specimens in all. Mr. Alston represented the Museum at the first South American Botanical Assembly at Rio de Janeiro last October, and later made an expedition across the north western corner of the South American continent from La Guayra in Venezuela to Bartacoas in southern Colombia, near the frontier of Ecuador. He studied the phytogeography of the area and collected specimens of the plants found.

Anthropology and Ethnology in Switzerland

The *Bulletin der Schweizerischen Gesellschaft für Anthropologie und Ethnologie*, 1938–39, in addition to the annual report, obituary and other affairs of domestic concern, contains matter of wider interest for anthropologists in a contribution by the editor, Dr. O. Schlaginhaufen, "Untersuchungen uber die Gesichtsform der Schweizer" which was presented to the International Congress of Anthropological and Ethnological Sciences at Copenhagen in August last, and summaries of the anthropological communications to the annual meeting of the Société Helvétique des Sciences Naturelles at Coire, August 28, 1938, from the *Actes* of that Society. Among these, a group of papers by Prof. E. Pittard deals comparatively with various lesser known physical characters of the Bushman and other peoples of South Africa, upon which the author's promised further interpretations will be awaited with considerable interest.

Students of the skeletal remains of man may be directed particularly to the study by Dr. Albert L. Périer of a remarkable postmortem deformation of the mandible in six out of a collection of twelve Griqua skulls. In these six specimens, the bicondylar diameter of the mandible is by so far less than the corresponding basio-cranial diameter that it is impossible to articulate the jaw to the skull; and indeed, if it were not for the correspondence of other characters, it would be difficult to believe that their attribution to these crania is correct. In three of the skulls the discrepancy in diameter is ten millimetres or more. It is to be noted that the bone of the jaw is exceptionally thick, and the shrinkage absolutely symmetrical. No acceptable explanation of the change presents itself, especially as no other example is found in one hundred and fifty South African skulls in the collection to which the Griqua skulls belong. The author points the moral that caution must be exercised in drawing conclusions from isolated specimens in human palæontology.

Tests of Materials

Numbers 726 and 727 of Hermann's "Actualités scientifique et industrielle" (Paris) deal with tests of materials and are entitled "La Structure et la Déformation des Solides" and "Essais des Métaux", respectively, the former of fifty pages (18 francs), the latter of seventy pages (25 francs), both well illustrated. They are written by M. R. L'Hermite, assistant director of the Laboratory for Buildings and Public Works, Paris, and represent his lectures delivered at the Laboratory in 1937 and 1938. He emphasizes the influence of the fine structure of materials on their elastic properties and devotes half the first volume to microscopic and X-ray methods and their results. In the section on the deformations produced by applied forces he makes use of the Mohr-Caquot diagrams and theory, and ascribes deviations of experimental results from the theory to want of isotropy. In the second volume many of the newer forms of machines for testing metals under tension, compression, shear, bending and shock are described, as well as methods of testing hardness, wear and fatigue. The principal results obtained are given and are related to the Mohr theory.

Bibliography of Seismology

This bibliography, by E. A. Hodgson, published by the Dominion Observatory, Ottawa, for the period October–December 1938 has just been received. It contains 120 items from fourteen collaborators residing in eight countries, and it is noticeable that the United States and Holland are well represented and that Spain has a collaborator. Italy, the Balkan States, the U.S.S.R. and South America are this time not represented although it is known that seismological work is being done in all these places. One of the more recently studied branches of the subject is well illustrated by a paper by A. Belluigi ("Seismisch-electrische Wirkungen und neu mogliche seismische Anwendungen", *Bei. Angew. Geoph.*, 7, Heft 3, 260–264, bib., Leipzig, 1938). It concerns the new seismic-electric effect pointed out by American authors, and the author suggests that its probable cause consists in electrochemical alterations produced by elastic waves as Thyssen, Hummel and Rülke have demonstrated. It is further suggested that new electro-elastic seismometers be planned, as these should afford advantages over the present seismometers in exactness of reproduction of impulses, owing to the absence of inertia masses, and they should measure at the same time the electrical resistivity. Following the bibliography is a very valuable double index for the whole year, arranged first by subjects and then by names

Journal of the Royal Agricultural Society

The *Journal of the Royal Agricultural Society of England* has reached its hundredth volume, and with this issue certain changes of format are being made. In place of the single annual volume, a periodical appearing three times a year is to be published. The first part, issued in June, consists mainly of the usual reviews of agricultural research under the familiar title, "The Farmer's Guide", but also includes the annual financial statement. Part 2 will appear in November and will contain a number of contributed articles and the various reports on the Show. Part 3 will be published in March and will also contain a number of contributed articles, the report of the Council to the annual general meeting, the annual reviews of agricultural law and agricultural statistics, and the annual report of the Society's scientific officers and of its research committees. Each part will include a summary of the proceedings of the Council at its meetings in the previous two or three months and will be separately indexed. The June issue for 1939 (100, Part 1) is now available and can be obtained from the Society, 16 Bedford Square, W.C.1, price 5*s*.

The Grid System

THE Association of Engineering and Shipbuilding Draughtsmen publishes (Draughtsman Publishing Co., Ltd., 96 St. George's Square, London, S.W.1) a series of pamphlets containing much useful information. A recent issue, entitled "The Grid System", contains a historical survey of electricity supply in Great Britain from the formation of the Edison Light Co. in London in 1881, through the troublous years when various Acts of Parliament were passed which in some cases hampered the industry; the first contracts for the 'grid-iron' or grid system were placed in the year 1928, and this was followed by the growth in the space of six years of 4,000 miles of transmission lines and the placing of 26,000 steel pylons. The advantages of standardizing frequency are discussed and the systems adopted for grid tariffs and trading. Much of the information is not readily obtainable elsewhere. A list is included of A.E.S.D. printed pamphlets and other publications written specially for engineering and shipbuilding draughtsmen.

Dutch Colonial Institute

THE "Acht en Twintigste Jaarverslag van het Koloniaal Instituut" gives a brief account of the work of the Dutch Colonial Institute at Amsterdam during the year 1938. Its activities have included public lectures, courses of instruction in tropical hygiene, researches on tropical diseases such as yellow fever and psittacosis, studies in mosquito control and the chemical examination of more than four thousand samples. The valuable work recorded in this year-book gives ample evidence that the Dutch Colonial Institute continues actively to serve the interests of Holland and its oversea possessions

The Scientific Films Committee

ABOUT two years ago the Association of Scientific Workers set up a Scientific Films Committee, to act as a clearing-house of information on scientific films. During this time it has seen and appraised some 150 films, and has produced a graded list of these films with particulars of length, availability, subject-matter, distributor, etc. This list is available to anyone interested at a cost of 1*s*. If desired, the Committee will undertake, for a small charge, to choose a programme to suit any particular requirements. In addition, the Committee has compiled an index of scientific and film experts willing to be put in touch with people requiring advice on the making of films. Full particulars of the services offered can be obtained from the Secretary, Scientific Films Committee, 30 Bedford Row, London, W.C.1.

Apparatus for the Physical Laboratory

THE twenty-fifth edition of the catalogue of physical laboratory apparatus and equipment recently issued by Messrs. W. and J. George, Ltd., proprietors of F. E. Becker and Co., London and Birmingham, is an impressive volume of 824 pages. The contents cover the whole of the equipment needed for the teaching of physics in all types of educational institution from elementary school to university. For convenience of reference, the catalogue is classified into thirteen sections within which the items are arranged in the usual text-book order of treatment of the subject. Physics is divided into ten sections. The remaining three deal with laboratory fittings, equipment and materials, with lantern slides, ciné films and with text-books. Out-of-date items have been entirely replaced by new apparatus, and the designs of many standard instruments have been improved. In addition to the well-known series of Nivoc products made by Messrs. George, other British and foreign items are included so that every normal requirement in physics teaching is to be found within the covers. But it is more than a mere catalogue. Each item dealing with less well-known apparatus has a brief description of the method of use, together with the necessary theory, supplemented in some of the entries by typical numerical results obtained with the apparatus in the laboratory. Some of these descriptions cover a page or two. The specially drawn illustrations are very clear and project well in the epidiascope. Altogether the catalogue, with its detailed index, corner page headings and numerous cross-references, makes a noteworthy addition to the library of any educational or industrial physics laboratory.

Book Reviews

SIDE by side with the increase in numbers of scientific papers which has been referred to repeatedly in this journal in recent years, there has been a steady if smaller growth of scientific and technical text-books, monographs and other books of interest to readers of NATURE, and the task of presenting to the scientific reader a reasoned survey of such literature has become increasingly difficult in the limited space available. Following the customary practice, longer notices of books have been printed under appropriate titles, while shorter notices have been brought together without a special heading; in addition, a classified list of recent scientific and technical books, whether received for notice in NATURE or not, is printed every month as a supplement to the journal. In the present issue, the shorter notices, which used to appear in the body of the journal immediately after the longer reviews, have been placed in the supplement with the books list. By publishing these shorter notices once a month in this way, it is possible to arrange them according to subject and it is also hoped to increase the total amount of space given to such notices. For the convenience of those who wish to bring the books lists together when binding up a volume, the list

SHORT REVIEWS

BIOLOGY

Everyday Biology:
an Introduction to the Study of Life. By Dr. G. Pugh Smith. Pp. xii+283. (London: G. Bell and Sons, Ltd., 1939.) 3*s.* 6*d.*

HERE is a very useful and readable introduction to biology written for young beginners who need a general survey of the subject prior to going into it more deeply for the School Certificate examination. The author has taken the point of view—unfortunately all too rare among authors and teachers of biology—that the subject should relate itself to life and thus teach the reader something about himself. Again, the author takes the refreshing course of opening up with a general review of the plant and animal kingdoms. So many biologies begin with a germinating seed or the detailed study of a plant, which more often bewilders rather than captivates the young beginner. To begin with a general survey of what is already known (at any rate, in part) is undoubtedly the best means of approaching a difficult subject.

The author has broken new ground, even in many of his illustrations, though here he is not so successful. Many are novel and look well, but they teach little. For example, the skeleton is illustrated by three photographs. One is of the "Transparent Woman", which, according to the legend, shows the "skeleton, organs and blood vessels and their relationship to each other". The actual model does this, of course; but the very much reduced photograph shows very little. The other two illustrations are X-ray photographs which will certainly intrigue the young beginner, but will tell him little of the actual anatomy of the skeleton. In the next edition, these photographs should be accompanied by a line drawing. Another excellent, though scarcely helpful, illustration is the photograph of the head of an earthworm which, without the help of the legend, would puzzle many a trained biologist.

In the second edition, the author would be well advised to reconsider certain of the illustrations (so important to any work on biology), and then it would be difficult to better this book for the standard for which it is intended.

Medical Entomology
A Survey of Insects and Allied Forms which Affect the Health of Man and Animals. By Dr. William A. Riley and Dr. Oskar A. Johannsen. (McGraw-Hill Publications in the Zoological Sciences.) Second edition. Pp. xiii+483. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 25*s.*

WE welcome the appearance of a second edition of this text-book. After an interval of six years much new knowledge has accumulated while older theories and facts have undergone modification. While only seven additional pages are incorporated in this volume, careful reading will show that the revision has been adequate and conscientious. Thus, the account of Latrodectus (or the 'black widow' spider) has been brought well up to date with new illustrations. The role of Phlebotomus in relation to the transmission of kala azar is well discussed, and the conclusion is reached that the insect-vector theory of the transmission of this disease is not borne out as being a major factor in the process.

In the account of mosquitoes an adequate statement of recent work on the biological and other races of these insects seems to be an omission of importance. In dealing with dipterous larvæ as agents in the treatment of osteomyelitis, reference is made to the newest aspect of this method. This involves the use of sterile larval extracts and the isolation therefrom of allantoin or the urea split off during allantoin treatment. In this way a definite advance seems to have been made in overcoming the repulsion aroused by the application of living larvæ to wounds.

In connexion with yellow fever a guarded account is given and a not too optimistic view taken as to its entire elimination from the American continent, owing to the prevalence of the disease in an endemic jungle form. In the great forests of Africa and South America, monkeys and maybe other non-human reservoirs have to be contended with, while various little-suspected species of mosquitoes are probable vectors. At the end of the book there is a supplementary list of literature which brings this aspect of the subject reasonably up to date.

Études et recherches sur les phytohormones

Première réunion organisée en collaboration avec l'Union Internationale des Sciences biologiques, Paris, 1 et 2 octobre 1937. Pp. xiv+126. (Paris: Institut International de Coopération Intellectuelle, 1938.) 35 francs.

IN spite of the great interest in the phytohormones which has been aroused in recent years, their mode of operation and full significance are still far from being fully understood. In the hope of clearing up some of the problems concerning them, and in order to discuss them generally, an international conference of experts who have specialized in the study of phytohomones was held at Paris in 1937. The conference was under the auspices of the International Union of Biological Sciences in collaboration with the International Institute for Intellectual Co-operation. Papers were read by each of the following: Prof. M. J. Sirks (introduction); Prof. F. Kögl (chemistry of phytohormones and other plant growth substances); Prof. Niels Nielsen (phytohormones in different groups of plants); Prof. V. J. Koningsberger (phytohormones and metabolism); Prof. G. S. Avery, jun. (the concept of phytohormones and their relationship to plant irritants); Prof. R. Bouillene (the action of phytohormones on growth, cell division and the genesis of organs); Prof. R. Boysen Jensen (phytohormones and plant movements); Mlle. C. Zollikofer (the influence of animal hormones on plants); Prof. R. Dostal (correlations and phytohormones). The report under review contains each of these papers in full, with an account of the discussions which followed. It is worthy of careful study by all those who are interested in this aspect of plant physiology.

C. R. M.

Methodik der Hormonforschung

Von Dr. Christian Bomskov. Band 2: Ovar (Follikehormone, Gelbkörperhormon), Hoden, Hypophysenvorderlappen. Pp. xxix+1016. (Leipzig: Georg Thieme, 1939.) 89 gold marks.

THE second volume of Bomskov's work on the methods used in research on hormones deals with the sex glands and the anterior lobe of the pituitary. A third volume dealing with the posterior lobe of the pituitary, the anti-pernicious anæmia factor and vasodilator substances is in preparation. This second volume has been produced in a year and a half, and it is easy to believe the author when he says in his preface that it has meant a great sacrifice of personal freedom. The book sets out to describe all the surgical, histological, biological and chemical methods used in the study of hormones. The details are usually given in the form of a direct translation from the original description, so that it is often unnecessary to refer to the original work. There are about 3,000 references, 274 beautifully reproduced figures and 276 tables.

This book will be an invaluable source of information to all workers in this field. It can be criticized on the ground that it contains too many facts. The full description of a number of different ways of doing the same thing necessarily involves a certain amount of repetition but increases the usefulness of the book. The writings of Dr. Bomskov have covered a very wide field (he has written a similar book on vitamins) and it is natural that those whose expert knowledge is deeper, but narrower, should find matter for criticism. Such general reviews do for scientific workers, however, what Baedeker has done for tourists: the traveller finds them very useful, and the settler prefers other sources of information, so long as he is in his own small field.

A Textbook of Pharmacognosy

By T. C. Denston. Third edition. Pp. xvi+583. (London: Sir Isaac Pitman and Sons, Ltd., 1939.) 20*s*. net.

THIS text-book is primarily intended for the use of students preparing for the chemist and druggist qualifying examination of the Pharmaceutical Society of Great Britain. The subject-matter covers the syllabus for this examination, and is arranged in a systematized, concise manner so that the student can readily grasp it. The drugs dealt with are classified according to their morphological nature under barks, roots, seeds, fruits, etc. This enables the student to compare and contrast similar morphological structures by their macroscopic characters. Microscopy is limited, so as to fulfil the above examination requirements, to starches, calcium oxalate crystals, epidermal trichomes, hairs and fibres used in surgical dressings, and filtering materials. Attention is given to recent work on the identifying and evaluation of drugs, the use of the ultra-violet lamp, methods of cultivation, collection, stabilization, drying, preservation and the detection of adulteration and of insect invasion. Reasons are given for the standards of purity laid down by the British Pharmacopœia.

The illustrations are numerous and of a high order. The drawings set a standard which students would do well to emulate. Both author and publishers have collaborated to produce a volume of which they may justly be proud, and which can be recommended with confidence to those for whom it is written.

W. O. Howarth.

An Introduction to Vertebrate Anatomy

By Harold Madison Messer. Pp. xvi+406. (New York: The Macmillan Company, 1938.) 16*s*. net.

IT is often profitable to present old knowledge in new ways, and this Prof. Messer has done by rejecting the method of teaching zoology by means of selected types and treating the systems of organs from a comparative point of view. The book is a compilation, and makes no claim to originality of knowledge or treatment. But the author maintains that the 'systemic method' is more satisfactory than the 'type-study method' both in the lecture room and the laboratory. The American student taking a one-year course is taught the comparative embryological, histological and anatomical aspects of each system of organs from cyclostomes to man, without, so far as can be ascertained from the book, studying a system in detail in any one animal or relating that system to the body as a whole. Herein, in the reviewer's opinion, lies the weakness of the method, since the elementary student has no standard or basis for comparison.

The book is well produced and contains some good photographs of stuffed and living animals from museums and zoos. The anatomical figures, however, are of variable quality, many being too small or too faintly drawn, or even so poor as to be misleading. The text, though on the whole well done, is at times inaccurate, perhaps as the result of pushing comparisons too far. A bibliography and glossary are appended.

N. B. Eales.

The Molluscs of South Australia

By Bernard C. Cotton and Frank K. Godfrey. Part 1: The Pelecypoda. (Handbooks of the Flora and Fauna of South Australia.) Pp. 314. (Adelaide: Government Printer, 1938.) 7*s*. 6*d*.

This book is the tenth in the series "Handbooks of the Flora and Fauna of South Australia". It is purely conchological and deals with the Pelecypoda. There is an introductory chapter on distribution and methods of collecting, and an account is given of the structure of a typical bivalve mollusc. Keys are used for tracing specimens to families, genera and species; but these are based on conchological characters only. The descriptive text is illustrated with good figures of the shells.

The object of this series is to provide Australian naturalists with inexpensive but accurate handbooks dealing with the indigenous flora and fauna. Many of the volumes are pioneer efforts, none more so than this one, for although great collectors like Angas, Tate and Verco have made lists or deposited specimens in the South Australian Museum, no comprehensive account of the bivalves has hitherto been published. The work of these two Adelaide city men deserves the highest praise from every naturalist, and we hope that it will inspire the production of a more scientific treatise on the group, for a bivalve without a body is a mere shell.

N. B. Eales.

Population: To-day's Question

By G. F. McCleary. Pp. 222. (London: George Allen and Unwin, Ltd., 1938.) 6*s*. net.

The author, who as former principal medical officer of the National Health Insurance Commission and medical officer of health of two London boroughs had ample opportunities of studying the various problems of population, has given a lively and lucid exposition of this subject in this little work. The historical aspects are first set forth, special attention, of course, being given to the work of Malthus, followed by an account of the modern methods of measuring the growth of the population. The author then discusses the causes of the great increase in population which began in the eighteenth century and continued until about sixty years ago, when a marked decline in the birth-rate began. Finally, the important subject of birth control receives full consideration, including its social, economic and political results.

Chemistry

The Chemical Formulary

A Collection of Valuable, Timely, Practical Commercial Formulæ and Recipes for making Thousands of Products in Many Fields of Industry. Vol. 4. Editor-in-Chief, H. Bennett. Pp. x+632. (London: Chapman and Hall, Ltd., 1939.) 25*s*. net.

To the three volumes of the "Chemical Formulary" there has now been added a fourth, in which are to be found many formulæ and recipes gathered together during the past year by members of a large editorial board. This American assembly of useful compounding information, obtained variously from commercial practice and from patent and general literature, covers a very wide range of products ranging from lipstick to lubricants, from concrete to cold cream, from solutions that entice an oyster open to a method for preparing a sulphuric acid catalyst.

In view of the wide application and use of compounded materials of all kinds, the value of a register such as this needs no emphasis. Intelligently used, it conveys a great deal of interesting information, and while it may not in every conceivable case specify the best possible admixture of ingredients for a particular purpose, it will nevertheless save the experimenter much time by presenting him with a reasonable starting point for his trials. The amateur researcher, endowed with that degree of skill, curiosity, and courage requisite for the purpose, will find much to interest him in the sections devoted to cosmetics, to beverages, liquors and flavours, to photography, and to the farm and garden. Engineers and chemists will find particularly valuable such sections as those on materials of construction, paints, soaps, emulsions, adhesives, and inks. The layman who has no intention of putting any of the recipes to a practical test will discover that with the aid of this book he can spend a profitable hour learning something of the composition and application of materials in everyday use.

A. A. E.

Lehrbuch der chemischen Physik

Von Prof. Arnold Eucken. Zweite vollkommen neubearbeitete Auflage. Band 1: Die korpuskularen Bausteine der Materie. Pp. xix+717. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1938.) 40 gold marks.

The new edition of Eucken's "Lehrbuch der chemischen Physik" is to be in two parts, of which this is the first. It deals with corpuscles and radiation, and the treatment is on the whole theoretical and mathematical. Several specialists have co-operated in the preparation of sections, some of which are more detailed and difficult than others. The basis is quantum-mechanical. Since the treatment includes molecules, there is a long account of valency. There are also detailed accounts of various types of spectra. The range of subjects is very large, so that a detailed account of the contents can scarcely be given, but the main object is to provide an account of the modern theories of atomic and molecular structure. The mathematics is, on the whole, of a standard which is within the capacity of an advanced student of physical chemistry, and the book contains a large amount of well-digested information. References to literature are given.

Annual Reports on the Progress of Chemistry for 1938

Vol. 35. Pp. xviii + 447. (London: Chemical Society, 1939.) 13*s*. net.

THE present issue of the "Annual Reports on the Progress of Chemistry", issued by the Chemical Society, contains sections on radioactivity and sub-atomic phenomena, general and physical chemistry, inorganic chemistry, crystallography, organic chemistry, biochemistry, and analytical chemistry. The plan of dealing with selected topics in some detail is adopted and the reports are interesting and valuable. Of the 410 pages of text, more than 100 are devoted to organic chemistry. This seems a very high proportion as compared with the other six parts of the book, and those responsible for the reports might well consider whether a better balance is not desirable. Some 50 pages on general and physical chemistry cannot be said to reflect the great importance of this branch of the subject.

Kurzes Lehrbuch der physikalischen Chemie

Von Prof. Dr. Hermann Ulich. Unter Mitarbeit von Dr. Kurt Cruse. Pp. xvi + 315. (Dresden und Leipzig: Theodor Steinkopff, 1938.) 12 gold marks.

THE distinguishing features of this book are the omission of material which belongs specially to physics and the illustration of the theory by numerical examples. A detailed consideration of the laws of thermodynamics, for example, is replaced by a brief but very clear and instructive discussion of the entropy as a measure of internal disorder, and the formulæ for maximum work and entropy changes are given in a very practical form. The calculations deal with systems of practical interest and are most instructive and helpful. Although the book is short it is in no way superficial or too elementary, and the emphasis is modern throughout. The brief biographical and historical notes add interest to the text. Particular care is taken to include English and American work, and the English names of functions, etc., are given. The bibliography is very well chosen, and for those students who can read German the book cannot fail to be helpful and stimulating.

The Chemical Analysis of Foods and Food Products

By Dr. Morris B. Jacobs. Pp. xxii + 537. (London: Macmillan and Co., Ltd., 1938.) 25*s*. net.

A GOOD book, full of details which the ordinary inquirer is not likely to find in the usual text-books. It should be on the shelves of every public analyst, and will be found of great use for purposes of reference.

Engineering

Testing Television Sets

By J. H. Reyner. Pp. viii + 128 + 12 plates. (London: Chapman and Hall, Ltd., 1938.) 9*s*. 6*d*. net.

THE inauguration of a television service in Great Britain has brought forth a number of text-books, not so much on the theory of the subject as on the very practical question of keeping receivers in effective operation. The complexity in a television receiving set might suggest that the liability to failure is high in comparison with normal broadcasting receivers. The fact is, however, that television sets are much better made, and the anticipated mass-faulting has not matured. The present text-book gives some indication how faults may be chased and put right, but we should not be doing the book justice if we stopped at that, because in illustrating the way in which the elementary parts might misfunction, the author does give much insight into the working of the several parts, so that a technician in a hurry to grasp a formidable subject can get some basic knowledge as well. The text is illustrated with rasters exhibiting typical faults and many clear diagrams.

L. E. C. H.

River Engineering: Principles and Practice

By F. Johnstone-Taylor. Second edition enlarged. Pp. xxii + 119. (London: The Technical Press, Ltd., 1938.) 4*s*. 6*d*. net.

TO deal with a subject such as river engineering within the limits of a small-sized text-book necessarily involves a considerable degree of compression, so that the author has only been able to touch lightly on certain aspects, which might with advantage have been treated at greater length. The explanation of the action of flow at river bends, for example, is rather too superficial to be altogether satisfactory. As a fairly representative outline of the various methods of treatment adopted for the regulation of river channels, the book may serve as a useful introduction to a more detailed study of a difficult science.

B. C.

Medicine

Recent Advances in Chemotherapy

By Dr. G. M. Findlay. Second edition. Pp. x + 523. (London: J. and A. Churchill, Ltd., 1939.) 21*s*.

THE series of books published by Messrs. J. and A. Churchill dealing with recent advances in the medical sciences has served a useful purpose and been deservedly popular, but they vary much in form. Some of them contain full reviews on selected topics, giving a readable and connected account of certain aspects of the science with which they deal; others tend rather to consist of abstracts of all the papers published on the subject in the last ten years, and give the impression of having been printed directly from a card index. The latter method of writing provides more information per page but less pleasure for the reader.

The information available on chemotherapy is fragmentary, though extensive, and few generalizations are possible, and the book under notice suffers from fragmentation and compression. Since the first edition appeared, the discovery of the action of sulphonamide derivatives on bacterial infections has opened up great possibilities and caused the appearance of a spate of literature. A new chapter with more than 150 pages which is devoted to this absorbing topic contains an enormous amount of information and greatly enhances the usefulness of the book.

Books on chemotherapy are few, and this one will be almost indispensable to those working on the subject. It contains a large number of references, many of them to papers written in 1938. It is a pity that several of the chemical formulæ are incorrectly printed.

The Extra Pharmacopoeia

By Martindale. Twenty-first edition. In 2 vols. Vol. 2. Pp. xxxvi+1148. (London: The Pharmaceutical Press, 1938.) 22*s.* 6*d.*

THE "Extra Pharmacopoeia" has been produced by the Pharmaceutical Society since the death of Dr. W. H. Martindale in 1933. The twenty-first edition is the first to be completely produced in this way and it is now completed by the issue of volume 2, which is considerably larger than the last volume 2. This volume contains 330 pages of analytical addenda to volume 1; comprehensive information about proprietary medicines, a new section on the nomenclature of organic compounds which contains information not readily available elsewhere; 70 pages of tests on blood and urine; sections on vitamins, milk, margarine, jam and various other foods; preservatives; 135 pages of clinical notes on various diseases; articles on chemotherapy, radium, X-rays, electrotherapy, and much information about chemical tests of all kinds. The book contains a vast amount of information and numerous references to recent medical literature. It has been brought thoroughly up to date and the revision must have involved much work. It will be useful not only to pharmacists but also to biochemists, medical men and analysts.

Classic Descriptions of Disease

With Biographical Sketches of the Authors. By Prof. Ralph H. Major. Second edition. Pp. xxx+727. (Springfield, Ill., and Baltimore, Md.: Charles C. Thomas; London: Baillière, Tindall and Cox, 1939.) 27*s.*

THE second edition of this fine volume contains nearly a hundred more pages than the first, which was published in 1932 (see NATURE, 131, 895; 1933). In addition to a general revision, new sections have been added on malaria, containing extracts from the works of Hippocrates, Aristophanes, Varro, Celsus, Pliny the Elder, Martial, A. F. A. King and Ronald Ross, and on yellow fever, to the knowledge of which Mathew Carey, Benjamin Rush, Carlos Finlay and Walter Reed, from whose works several passages have been selected, made such valuable contributions.

MISCELLANY

The Science of Society

An Introduction to Sociology. By Dr. J. Rumney. Pp. 125. (London: Gerald Duckworth and Co., Ltd., 1938.) 3*s.* 6*d.* net.

IN these days, few scientific workers can afford to be indifferent to sociology, whether or not they are convinced as to the possibility of a science of society. Even if they are concerned merely in planning in its narrowest technical sense, planning presupposes some understanding of the structure of society and the intimate interrelation between social life and material techniques, and the inability to realize the importance of a sociological approach lies behind many of the gravest difficulties of our time, such as unemployment, the revolt against democracy, mechanized or commercialized leisure, and blind resentment towards science because the benefits it was expected to bring have either not materialized or largely been missed. In this volume, Dr. Rumney indicates for the general reader not only the content of sociology, but also its possibilities as a practical instrument no less than for theoretical purposes.

The sociologist firmly believes that the scientific study of human affairs will ultimately provide a body of knowledge and principles that will facilitate the control and improvement of social conditions. His first task is to determine the range and structure of human society and of social institutions; the second is to investigate the nature of the interdependence of the structures that function in social life; and the third to establish empirical generalizations, or laws of change and growth in social life, and if possible to interpret them in the light of more ultimate laws. Dr. Rumney does not disguise the difficulties in the methods and technique of social study, and he stresses the importance of objectivity and the elimination of bias, as well as the absurdity of expecting the methods of social science to conform exactly to those of the abstract sciences. This brief account is eminently readable, not only for its avoidance of jargon, but also for the admirable way in which it discusses some of the biological aspects of sociology, such as the absurd racial claims sometimes advanced to-day, and the biology of war. Dr. Rumney gives a clear but brief account of the limitations no less than the opportunities of social study, and his book can be heartily recommended to the scientific worker. R. B.

The Consumer-Buyer and the Market

By Jessie V. Coles. Pp. xviii+596. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 17*s.* 6*d.* net.

UP to the time of the great depression in the United States, the average wage-earner there was more concerned with increasing his money income than his real income. During the depression millions of families were forced, in the attempt to maintain customary standards of living on falling incomes, to search for 100 cents' value in every dollar spent. As a result, there has been a steady growth of interest in the problems of the consumer, and the present volume is a comprehensive study of the difficulties that beset him (or her, as the case may be) in obtaining the desired goods at the lowest price.

The author deals first with the buying habits of the consumer and the structure of the retail market, in which connexion some interesting statistics are given of the comparative costs of marketing commodities by various methods and through various types of shop. Sections on instalment buying and retailers' price policy lead up to the most valuable part of the book, the section on "Market Devices as Aids to Consumer-buyers". After reading this account of the salesmanship, labelling, packaging, guaranteeing, branding and advertising of goods, one is forced to the conclusion that the main purpose of all these 'market devices' is the deception of the consumer. The inadequacy of legislative protection has given rise to such organizations as Consumers' Research, which seeks to provide confidential information on the relative merits of advertised or branded goods. R. W.

A Short History of Science

By Dr. F. Sherwood Taylor. Pp. xiv+320+14 plates. (London and Toronto: William Heinemann, Ltd., n.d.) 8*s.* 6*d.* net.

AN attempt to cover the history of science in some three hundred pages is bound to produce a result which can be criticized from one angle or another. The present book is probably as good an account as is possible in the space. The earlier chapters are of a more general character and will perhaps appeal most to the general reader, but even in the account of the later period, when the material is overwhelming, the author has managed to select with good judgment and to convey the story in a connected fashion. The book is one which should have a wide appeal. The interesting illustrations require special praise.

PHILOSOPHY

On Understanding Physics

By Prof. W. H. Watson. Pp. xii+146. (Cambridge: At the University Press, 1938.) 7*s.* 6*d.* net.

IN this work, Prof. Watson thinks aloud about some fundamental concepts and theories of modern physics. He uses for this purpose the analytical method favoured and practised by Dr. Wittgenstein, with the result that many questions, such as those of atomic mechanics and electricity, regarded mainly as mathematical or physical, resolve themselves into logical problems. There is no doubt that science does benefit from a systematic clarification of its language. But is it not going beyond this achievement to separate science entirely from philosophy? Language and symbols cannot go beyond themselves, so to speak, in representing the world of the physicist; but that should be no reason for denying value to *what* is represented. Such a value, of course, cannot be found within the restricted world of linguistic expression, especially in so far as it is applied to technically physical concepts. That is why Prof. Watson's conclusions from his discussion of the idea of substance (ch. v) seem to be beside the point. Nevertheless, the new ground broken in his book makes it a most useful contribution to the philosophy of Nature. T. G.

Symbolism and Belief

By Edwyn Bevan. (Gifford Lectures.) Pp. 391. (London: George Allen and Unwin, Ltd., 1938.) 15*s.* net.

THE philosophy of symbols has become prominent lately through the efforts of mathematical logicians. But it is not with that aspect of the subject which the book under review deals. The author is concerned with the relations between symbolism and religious beliefs. The very character of the data of revelation makes it necessary for man to use symbols for their interpretation and communication. In this respect Mr. Bevan performs a very useful task in explaining, with the support of an amazing amount of scholarship, the purpose of symbolism in these matters. His points would have been strengthened, however, by a bolder theory of analogy. As it is, his book enlightens us, but has little drive in it to guide us towards those truths which underlie his theme. T. G.

PHYSICS

Heat and Thermodynamics

An Intermediate Textbook for Students of Physics, Chemistry and Engineering. By Prof. Mark W. Zemansky. Pp. xii+388. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 24*s.*

THIS text is well suited to the needs of first-year honours students in physics and to students taking a graduate course in engineering. Experimental methods are cut down to the shortest possible presentation consistent with clearness, and modern methods are in most instances selected. Thus, the description of the time-honoured experiments of Joule and of Rowlands for the determination of J is cut down to a few words, and Callendar and Barnes, Jaeger and Steinwehr, and Laby and Hercus appear in their place. Forbes and Angström disappear, and a short account of the modern simple methods for conductivity determinations reigns instead.

Of the two partners in the title, thermodynamics has the lion's share of the space. The treatment is elementary, detailed and satisfactory; unavailable energy is correlated with entropy, and a number of special problems are discussed, including the phase rule. Applications of the Helmholtz and Gibbs functions are made, and a special chapter is devoted to the steam-engine and the refrigerator. Newton's law of cooling is deduced from the fourth power law as holding for small temperature excesses. The fact is, that Newton's law, in the circumstances in which it was established by Newton (*forced* convection), holds, as he showed it to hold, for temperature excesses of some hundreds of degrees.

Each of the nineteen chapters of the book is followed by a comprehensive set of numerical exercises, and the book may be commended as a careful and scholarly introduction to the subject, providing a solid foundation for further knowledge.

Demonstration Experiments in Physics

(Prepared under the Auspices of the American Association of Physics Teachers.) Edited by Prof. Richard Manliffe Sutton. Pp. viii+545. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 25*s*. net.

THERE are some books that can be reviewed at first reading, others that require only a glance. But sometimes the value of a book can only be appreciated when it has been used for some time, and then comes to be appreciated more and more. The author modestly claims "Demonstration Experiments in Physics" as a 'cookbook' for teachers of physics, and in its 500-odd pages it certainly contains an enormous variety of recipes. Among them we find many already familiar to teachers of physics in Great Britain, but the majority are new, or improved variants of existing experiments. They cover all branches of physics and all stages of lectures; but, naturally for demonstration experiments, the general emphasis is on the first and second years' lectures. Here dramatic nature of the action and simplicity of construction are the chief requirements. The reviewer can vouch for the feasibility of construction and the satisfactory performance of a considerable number of the experiments in this book.

The author and his collaborators have considered very carefully the principles underlying demonstration experiments, and their statement, which starts with the elementary fact so often forgotten that demonstrations are for the student and not for the instructor, is in itself a very useful contribution to the teaching of physics. Any physics teacher who buys this book is likely to find it of ever-increasing use in his lecture preparations.

The Flow of Homogeneous Fluids through Porous Media

By Dr. M. Muskat. With an Introductory Chapter by R. D. Wyckoff. (International Series in Physics.) Pp. xix+763. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 45*s*.

DR. M. MUSKAT'S book is an important contribution to technical literature and will be useful not only to workers in the oil and gas industries, but also to those who have to deal with problems of fluid flow through refractories and through ceramic materials and with problems of well and dam construction.

The eleven chapters which comprise the book are collected under four main headings. Part 1, which deals with fundamentals, is concerned chiefly with a discussion of Darcy's law connecting the rate of flow of water through a filter bed with the area of the sand, the thickness of the bed, and the difference between the fluid heads at the inlet and outlet faces of the bed. The law and its implications are very fully discussed, and the hydrodynamical equations for flow through porous media established. Part 2 deals with steady-state flow of liquids and contains discussions of two- and three-dimensional flow problems, of gravity-flow systems, of systems of non-uniform permeability, of two-fluid and of multiple-well systems. Part 3 is concerned with the flow of compressible liquids through porous media, and Part 4 with the flow of gases through porous media.

The treatment throughout is clear and detailed, and the whole work forms a most useful and praiseworthy contribution to a subject which had, until its appearance, scarcely been explored systematically.

An Introduction to Industrial Rheology

By Dr. G. W. Scott Blair. Pp. xiii+143. (London: J. and A. Churchill, Ltd., 1938.) 7*s*. 6*d*.

DR. SCOTT BLAIR deals mainly with the flow of non-Newtonian liquids: that is, those whose apparent viscosity varies with the rate of shear. We may regard these cases of anomalous viscosity from either of two points of view: that the anomaly is the interference with the normal hydrodynamical flow of the solvent by the solute particles; or, we may treat the system as a close-packed 'pudding' of particles separated by the dispersion medium. The latter, which is followed in this book, automatically becomes the method of approach of many industrial problems, since these are problems of the 'body' of systems in which the concentration of disperse phase is large. It is certain that, for dilute systems, the coaxial cylinder viscometer is preferable for theoretical reasons which are fundamental and well known.

That this is not made clear in this book is almost inevitable from the treatment followed. Viscosity is described from consideration of flow of liquids through tubes. This leads to Bingham's work on anomalous systems and to the subsequent modifications of his equation. Commercial viscometers are described, but the coaxial cylinder instrument is misnamed 'concentric' throughout the book. Although attention is mainly concentrated on paste type systems, the book contains a wide survey of all the types of anomalous liquid which have been investigated. It should be of value to industrial chemists faced with problems of anomalous viscosity, the number of which increases every day.

The Amplification and Distribution of Sound

By A. E. Greenlees. Pp. 254. (London: Chapman and Hall, Ltd., 1938.) 10*s*. 6*d*. net.

THIS is the first comprehensive text to appear on a subject which the public is rather apt to take very much for granted, the microphone-amplifier-loudspeaker combination, the correct and original description of which is the public-address system. There is little theory which can be said to belong to the subject, except the simple calculations associated with decibels, transformers, and the power-handling capacity of power-valves. The author concentrates on the practical side, perhaps too much, with rather crude descriptions of standard types of microphones and loudspeakers. Nevertheless, he does give a very good picture of the importance of the subject and the extent of its applications.

L. E. C. H.

TECHNOLOGY

An Introduction to the Study of Spinning

By Prof. W. E. Morton. Pp. viii+267. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 12*s*. 6*d*. net.

THE application of the exact sciences to problems of the textile industries has received special attention during this century. The research associations established in connexion with the industry and the Textile Institute, the professional institution of the industry, have contributed much to new methods of thought on textile problems. These organizations, together with the technical institutions responsible for the training of textile students, have created a demand that, as Prof. Morton puts it, the teaching of spinning should be developed on a broader basis.

In his excellent treatise under notice, Prof. Morton has adopted an entirely new method of approach. The book is divided into two parts. In the first part he gives a general survey of the various natural and synthetic fibres, while in the second part he deals with general spinning principles, and points out the modifications in method which the different types of material entail. The book is described by the author as primarily intended as a text-book for use during the first year or two of spinning courses. There is little doubt that in this direction it will have supplied a real need. It is, however, likely to have a much wider appeal, and it will be read by many engaged in the different branches of the textile industry. Its originality of conception and the skill with which it deals with a difficult and extensive subject make it a useful contribution to textile literature.

The Structure of Steel Simply Explained

By Eric N. Simons and Dr. Edwin Gregory. Pp. xi+115+7 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1938.) 3*s*. 6*d*. net.

THE subject of the structures of steels is one of very considerable importance from many points of view, and the present volume will be welcomed by many readers. It gives a very clear and intelligible account of the subject and is well illustrated. The treatment is both physico-chemical and practical, the properties of interest to engineers being fully explained as well as the effects of heat-treatment, and many difficult points are elucidated. The book may be warmly recommended. The treatment is 'simple' only in the respect that the authors have taken pains to remove difficulties, and the standard is high. The plates of microstructure are very good, and the properties of special steels receive adequate treatment.

TRAVEL

Saga of the *Discovery*

By L. C. Bernacchi. Pp. xv+240+48 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1938.) 10*s*. 6*d*. net.

THIS book is of particular interest since it is written by one of the few whose experiences date from the time when there were no vitamins or radio and when British polar explorers were expected to man-haul their sledges in the way so vividly described. One can well understand the wonder of an expedition to a region which, except for the merest fringe, was new and contained so much of the entirely unknown.

Commander Bernacchi has written of his companions with a sympathetic and notably unbiased pen—a gratifying characteristic—and in spite of his frank recognition of idiosyncrasy one is pleased to observe that he can still write that *Discovery* was a "happy ship". The prejudice against dog-haulage is dealt with, and it is easy to see that it made inevitable the tragedy which involved *Terra Nova's* polar party. It is a dreadful example of the destructiveness of the preconceived idea.

There are a few minor inaccuracies; for example, one may be permitted to doubt whether Killer whales attack adult Blues, since precisely similar stories are told with reference to the Greenland whale.

This is a very readable book and the author is to be congratulated not only for a history of a ship now withdrawn beyond the possibility of further work in the ice, but also for the record of his own experiences in the 'heroic age' of Antarctic exploration.

Siberian Man and Mammoth

By E. W. Pfizenmeyer. Translated from the German by Muriel D. Simpson. Pp. xii+256+24 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1939.) 12*s*. 6*d*. net.

DR. PFIZENMEYER here gives an account of two expeditions, of which he was a member, one in 1901–2 and one in 1908, that were sent to Siberia by the Russian Academy of Sciences to excavate the carcasses of mammoths, of which the discovery in a frozen state had been reported. Of these expeditions the first recovered the Bereskova specimen, the most complete hitherto known, and the second the Sanga-Yurakh mammoth, which determined previously uncertain details in the characters of the trunk and tail. The author reviews the history of discoveries of the mammoth since the first recorded report in 1698 down to his own expeditions.

It is somewhat remarkable that these discoveries aroused little scientific interest, and it was not until 1806 that anything like a complete specimen reached St. Petersburg. The character of the tusks was still uncertain, as the native tribesmen usually made a practice, when a carcass was discovered, of hacking out and cutting up the tusks for the sake of the ivory.

The narrative is not confined to the purely scientific objective of the expeditions; and the author gives a vivid picture of travel on horseback and by sledge in pre-Soviet Siberia. He had a sharp eye for the idiosyncrasies of the exiles and tribesmen with whom he came into contact, and gives an interesting account of shamanistic ceremonies and practices. His acute estimate of the potentialities of a country of great natural wealth seems on the way to be realized.

has been arranged as usual in the middle of the supplement, the pagination of which will be unaffected by its removal.

American Geographical Society Awards

According to *Science*, the American Geographical Society has made the following awards: Cullum Geographical Medal for 1938 to Emmanuel de Martonne, professor of geography at the University of Paris; Charles P. Daly Medal for 1939 to Prof. H. J. Fleure, professor of geography in the University of Manchester; David Livingstone Centenary Medal for 1939 to John R. Rymill, in recognition of his scientific achievement and exploration in the southern hemisphere. The following have been made honorary members of the Society: Sir Wilfred Grenfell, for his contributions to geographical knowledge concerning the Labrador Peninsula; Prof. H. Baulig, professor of geography in the University of Strasbourg, and Prof. G. Dainelli, professor of geology and physical geography in the University of Florence. The following have been made corresponding members of the Society: E. Antevs, research associate of the Carnegie Institution of Washington; Prof. L. L. Mecking, professor of geography at the University of Münster; W. E. Rudolph, a civil engineer who has carried out extensive explorations in South America; P. G. Schott, retired section chief of the Deutsche Seewarte and honorary professor in the University of Hamburg, and Dr. L. Dudley Stamp, reader in economic geography in the University of London and director of the Land Utilization Survey of Great Britain.

The Night Sky in August

The moon is new on August 15 at 3·9h. U.T. and full on August 29 at 22·1h. On August 25, ρ Sagittarii (magnitude 4·0) is occulted, the disappearance as seen from Greenwich taking place at 23h. 48·9m. at position angle 77° from the north point of the moon's disk. Conjunctions between moon and planets occur as follows: August 5d. 14h. with Jupiter; 7d. 9h. with Saturn; 26d. 14h. with Mars. On August 25 at 20h. Venus is in conjunction with Regulus, the geocentric distance between the planet and the star being 0·9°. Mars, Jupiter and Saturn rise in the evening, the respective times of southing on August 1 being 23h. 23m., 3h. 55m., and 5h. 20m.; by August 25 these times have changed to 21h. 35m., 2h. 17m. and 3h. 46m. Mars, a conspicuous object low in the evening sky, declines in brightness during the month from mag. −2·5 to −1·8; Jupiter increases slightly from mag. −2·3 to −2·4. Mercury reaches its greatest western elongation (18°) on August 28 and should be looked for in the early morning at about this date. Venus continues as a morning star rising in the dawn at 3h. 26m. on August 1 and at 4h. 38m. on August 25. Saturn reaches a stationary point on August 14, Mercury on August 20, Mars on August 24 and Uranus on August 28. The minor planet Juno is in opposition on August 19, when its magnitude is 8·3; on August 1 it is about 50′ south of α Aquarii. The Perseids reach their maximum frequency on or about August 9, their radiant point being near η Persei. In the late evenings of mid-August, with the moon absent, the region of the Milky Way near the southern meridian offers interesting 'sweeps' with binoculars or telescope.

Announcements

Prof. S. Timoshenko, professor of mechanics at Stanford University, California, has been elected *correspondant* for the Section of Mechanics of the Paris Academy of Sciences.

Mr. R. H. Whitby, City and Guilds College, London, has been awarded the Busk studentship in aeronautics for the year 1939–40 tenable at the Aeronautics Department, Engineering Laboratory, Cambridge.

The following awards for 1939–40 have been made by the Salters' Institute of Industrial Chemistry and approved by the Court of the Salters' Company. Fellowships have been renewed in the case of Messrs. A. Cameron (University of Cambridge), H. S. Corran (University of Cambridge) and J. L. Tuck (University of Oxford). Fellowships have been awarded to R. Scarisbrick (University of Cambridge), T. W. Walker (University of London) and J. A. Berriman (University of Cambridge). The Salters' Institute has also awarded forty-four grants-in-aid to young men employed in chemical works in or near London to assist them in their studies.

Prof. Otto Grossern, director of the Anatomical Institute of the German University of Prague, has been awarded the Silver Medal of 1939 by the Jena Society of Medicine and Natural Sciences.

Prof. Esmond R. Long, director of the Henry Phipps Institute and professor of pathology in the University of Pennsylvania, has been elected president of the Wistar Institute of Anatomy and Biology. Dr. Edmond J. Farris, associate in anatomy, in charge of operations at the Wistar Institute, is to be executive director.

The twelfth International Congress of the History of Medicine will be held in Berlin on September 22–28, 1940, when the chief subjects for discussion will be the evolution of medicine in different countries from Harvey to Haller (epoch of medical philosophers) introduced by Dr. Laignel-Lavastine, professor of the history of medicine in the Paris faculty, and the history of typhus, introduced by Prof. Zeiss, director of the Institute of Hygiene of the University of Berlin.

An account of the chemical composition of 'Volpar' contraceptive products recently published (*Eugenics Rev.*, 31, No. 1) gives many details about the nature and action of these substances. They are in the form of gels and pastes and are weakly alkaline, containing phenyl mercuric acetate in aqueous solution. The gels contain also glyceryl monoricinoleate together with a fungicide to prevent the action of bacteria and moulds. The paste contains a basis of arrowroot starch and can be used in the tropics. Numerous tests of their efficiency and other effects have been made on animals.

Nuclear Reactions in the Continuous Energy Region

IT is typical for nuclear reactions initiated by collisions or radiation that they may, to a large extent, be considered as taking place in two steps: the formation of a highly excited compound system and its subsequent disintegration or radiative transition to a less excited state. We denote by A, B, . . . the possible alternative products of the reaction, specified by the nature, internal quantum state, and spin direction both of the emitted particle or photon and of the residual nucleus and the orbital momentum. Further, we call P_A, P_B . . . the probabilities, per unit time, of transitions to A, B, . . . respectively, from the compound state.

The cross-section for the reaction $A \rightarrow B$ is then evidently

$$\sigma^A_B = \sigma^A \frac{P_B}{P_A + P_B + \cdots}, \qquad (1)$$

where σ^A is the cross-section for a collision in which, starting from the state A, a compound nucleus is produced. This formula implies, of course, that we are dealing with energies for which the compound nucleus can actually exist, that is, that we are either in a region of continuous energy values or, if the levels are discrete, that we are at optimum resonance. Moreover, it is assumed that all possible reactions, including scattering, proceed by way of the compound state, neglecting, in particular, the influence of the so-called 'potential scattering', where the particle is deflected without actually getting into close interaction with the individual constituents of the original nucleus.

On these assumptions a very general conservation theorem of wave mechanics[1] yields the relation

$$\sigma^A = \frac{\lambda^2}{\pi}(2l+1)\frac{P_A}{P_A + P_B + \cdots}, \qquad (2)$$

where λ is the wave-length of the incident particle and l is the angular momentum.

In the case of discrete levels, (1) and (2) give the same cross-section as the usual dispersion formula, if one applies it to the centre of a resonance level and neglects the influence of all other levels. In this case we have for each resonance level a well-defined quantum state of the compound nucleus, and its properties, in particular the probabilities P_A, P_B, . . . then cannot depend on the kind of collision by which it has been formed, that is, they would be the same if we had started from the fragments B, or C, . . . instead of A.

In the case of the continuum, however, where there are many quantum states with energies that are indistinguishable within the life-time of the compound nucleus, the actual state of the system is a superposition of several quantum states and its properties depend on their phase relations, and hence on the process by which the compound nucleus has been produced.

This dependence is made particularly obvious if we consider the formula

$$\overline{\sigma^A} = \frac{\hbar}{2}\rho\lambda^2(2l+1)P^0_A, \qquad (3)$$

for the mean value of the cross-section over an interval containing many levels, which follows from the well-known considerations of detailed balancing. Here ρ is the density per unit energy of levels (of suitable angular momentum and symmetry) of the compound nucleus. P^0_A is the probability for process A in statistical equilibrium and thus refers to a microcanonical ensemble of compound states built up from the fragments A, B . . . respectively, with proper statistical weights.

In the case of discrete levels, where formula (3) can also be derived directly from the dispersion formula, P^0_A is simply an average over the individual levels of the probability P_A, which in this case is well defined.

In the continuum, (3) must be identical with (2), since the cross-section does not vary appreciably over an energy interval containing many levels, and hence, comparing (2) and (3)

$$\frac{P^{(A)}_A}{P^0_A} = \frac{\pi}{2}\bar{\lambda}\rho\,(P^{(A)}_A + P^{(A)}_B + \ldots) = \frac{\pi}{2}\frac{\Gamma^{(A)}}{d}, \qquad (4)$$

where the superscript A has been added to the probabilities occurring in (1) in order to show explicitly the dependence on the mode of formation, and where $\Gamma^{(A)}$ is the total energy width of the compound state concerned and $d = \frac{1}{\rho}$ the average level distance. In the continuum, where $\Gamma^{(A)} \gg d$, the probability $P^{(A)}_A$ of re-emitting the incident particle without change of state of the nucleus will thus be much larger than the probability of the same process in a compound nucleus produced in other ways.

While the arguments used so far are of a very general character, more detailed considerations of the mechanism of nuclear excitation are required for a discussion of the dependence $P^{(A)}_B$ of the mode A of the compound nucleus provided $A = B$.

One can think of cases in which such a dependence must obviously be expected; in fact, if a large system be hit by a fast particle, the energy of excitation might be localized in the neighbourhood of the point of impact, and the escape of fast particles from this neighbourhood may be more probable than in statistical equilibrium. Further, if the system had modes of vibration very loosely coupled, the excitation of one of them, for example by radiation, would be unlikely to lead to the excitation of a state of vibration made up of very different normal modes, even though the state may be quite strongly represented in statistical equilibrium.

In actual nuclei, however, the motion cannot be described in terms of loosely coupled vibrations, nor would one expect localization of the excitation energy to be of importance in nuclear reactions of moderate energy. If we suppose that there are no other special circumstances which would lead to a dependence of $P^{(A)}_{B}$ on A, it is thus a reasonable idealization to assume that, even in the continuum, all $P^{(A)}_{B}$ are equal to P^{0}_{B}, except, of course, for $A = B$, where we have seen in (4) that the phases are necessarily such as to favour the re-emission of the incident particle.

A typical case of a reaction in the continuum is the nuclear photo-effect in heavy elements, produced by γ-rays of about 17 mv. In the first experiments of Bothe and Gentner, there seemed to be marked differences between the cross-sections of different elements, but the continuation of their investigations[2] indicated that these differences can be accounted for by the different radioactive properties of the residual nuclei, and that the cross-sections of all heavy nuclei for photo-effect are of the order of 5×10^{-26} cm.^{2}.

In previous discussions, based on formulæ (1) and (2), where the distinction between $P^{(A)}_{A}$ and P^{0}_{A} was not clearly recognized, it was found difficult, however, to account for photo-effect cross-sections of this magnitude. In fact, if one estimates the probability of neutron escape P_B at about 10^{17} sec.$^{-1}$, one should have for P_A 10^{15} sec.$^{-1}$, and as long as this was taken as P^{0}_{A} it seemed much too large, since it evidently must be much smaller than the total radiation probability, estimated at about 10^{16}, which included transitions to many more final levels besides the ground state.

We see now, however, that $P^{(A)}_{A}$ is here considerably larger than P^{0}_{A}, since the level distance at the high excitations concerned is probably of the order of 1 volt, whereas the level width corresponding to the above value of P_B is about 100 volts. From (4), or more directly from (3), P^{0}_{A} is thus seen to be only about 10^{13} sec.$^{-1}$, which would appear quite reasonable.

The Scattering by Uranium Nuclei of Fast Neutrons and the Possible Neutron Emission Resulting from Fission

THIS work to be described concerns only fast neutrons, and its object is the study of their scattering by uranium and the possible neutron emission which accompanies the fission of the nucleus.

The experiments were performed with a polonium plus beryllium source equivalent to 3mC. of radon plus beryllium. An ionization chamber surrounded with 2·5 cm. lead, filled with hydrogen at a pressure of 35 atm., was used as a neutron detector. The insulated electrode was connected to a compensated electrometer valve[1], the grid leak being 10^{11} ohms and the sensitivity $1{\cdot}2 \times 10^{-15}$ amp./div. on the scale.

We have employed two experimental arrangements in which the source was placed (1) between the chamber and the substance used as scatterer, the nature and the thickness of which were variable; (2) in the centre of a cube of 16 cm. side, alternately filled with uranium oxide (specific gravity, $d = 4{\cdot}0$) and lead oxide (compressed to $d = 3{\cdot}8$).

The first type of experiment gave us the total scattering cross-section, which is, as can be shown, $\sigma_t = \sigma_e + k_i\sigma_i$; for uranium oxide $\sigma_t = \sigma_e + k_i\sigma_i + k_r\nu_r\sigma_r$, where σ_e, σ_i, σ_r are respectively the average cross-sections of elastic and inelastic scattering and of fission; ν_r is the average number of neutrons produced per fission; k_i and k_r are the average efficiency factors of the chamber for the neutrons having undergone an inelastic collision or for the neutrons resulting from fission. The efficiency for the direct neutrons was taken to be unity, $k = 1$. For neutrons elastically scattered by nuclei of sufficiently high mass, $k_e = k = 1$. We have calculated k, taking into account the size of the chamber, the cross-section for proton projection, etc. The spectrum of polonium plus beryllium neutrons has been considered[2] to contain 50 per cent of neutrons of W_n less than 10^6 ev. We thus obtain:

$10^{-6}\,W_n$	0·1	0·5	2	5	10 ev.
k	0·3	1	1·9	1·7	1·2

In view of a possible extrapolation that would give $\sigma_e + k_i\sigma_i$ for uranium, we have in the same way experimented with scattering by lead oxide, lead, copper and zinc.

The results of the first experiment were as follows:

Substance	Cu	Zn	Pb	PbO_2	UO_2	$(O)_{calc.}$	$(U)_{calc.}$
$\sigma_t \times 10^{-24}$ cm.^{2} ($\pm$ 10%)	2·2	2·3	5·4	9·5	14·4	2	10·3

The values for uranium and oxygen are calculated on the assumption of the additivity of the cross-sections in lead oxide and uranium oxide.

The second experiment gives us, in the first approximation, the absorption coefficient $(1-k_i)\sigma_i + (1-k_r\nu_r)\sigma_r$, the value of σ_e being only as a correction term in the determination of the mean free path λ and the average distance L travelled by the neutrons before they escape from the whole mass, which is supposed spherical, the radius being r and $L = r\left(1 + \frac{1}{2}\frac{r}{\lambda}\right)$. This experiment, taking into account the results of the previous experiments, gives for lead, $(1-k_i)\sigma_i \simeq 2 \times 10^{-24}$ cm.^{2}. Assuming that σ_i can reach 30 per cent of σ_e[3], this gives k_i ($\simeq$) 0.

With the exception of uranium, for which one must consider not only σ_i, but also $\nu_r\sigma_r$, it is probable that σ_t is not very different from σ_e because of the small value of k_i.

In the case of uranium, however, we have,

$$(1-k_i)\sigma_i + (1-k_r\nu_r)\sigma_r \simeq 0{\cdot}9 \times 10^{-24}\ \text{cm.}^2 \quad (1),$$

or, by adding to σ_t, thus eliminating k_i and k_r,

$$\sigma_e + \sigma_i + \sigma_r \simeq 11{\cdot}2 \times 10^{-24}\ \text{cm.}^2. \quad (2).$$

If it is supposed that each fission produces radio-elements, the cross-section measured by Joliot, and by Anderson *et al.*[4] would be identical with σ_r, which they found to be $\sigma_r \simeq 10^{-25}$ cm.^{2}. In this case we see that $(\sigma_e + \sigma_i)$ is much greater ($\simeq 11{\cdot}1 \times 10^{-24}$ cm.^{2}) than that given by an extrapolation ($\simeq 6 \times 10^{-24}$ cm.^{2}).

On the other hand, it results from (1) that, if the value of σ_i is comparable to that of the next elements (1 to 2×10^{-24} cm.^{2}), ν_r can, with plausible assumptions as to the coefficients k_i and k_r, take variable values, for example, from 1 to 5, or even more.

One can see that, so long as σ_i is not determined separately, the experiments of the type described do not allow us to determine ν_r and σ_r (characteristics of the fission), or to conclude that neutrons are liberated; or, *a fortiori*, to form a conclusion as to the possibility of chain reactions, contrary to the results of similar experiments[4].

The only suitable case for showing with certainty, by means of an ionization chamber, the production of neutrons, would be that in which, by the use of a sufficient quantity of uranium, the chain mechanism would give multiplication of neutrons, if such chain is realizable[6].

In conclusion, it results from these experiments with neutrons of polonium plus beryllium that the sum of the cross-sections $\sigma_e + \sigma_i + \sigma_r$ for the uranium nucleus is $(11\cdot2 \pm 1\cdot5)10^{-24}$ cm.[1]. This value implies a mean path in uranium much shorter than that usually admitted; this suggests that smaller masses than those hitherto expected might be used to show chain fission.

Possible Delay in the Emission of Neutrons from Uranium

ROBERTS[1] and others have reported the emission of delayed neutrons with a period of 12 sec. from uranium under neutron bombardment, but the effect seems to be a small one[2], the main body of neutrons being produced in a much shorter period. Green and Alvarez have shown that there is no delay exceeding 3×10^{-9} sec. in the actual production of fission, but it seemed possible that the neutrons might not be produced at the moment of fission but rather as the products of rapid disintegration of the primary fission particles.

Following on a conversation with Prof. N. Bohr, we have made experiments to see if there is any appreciable delay (approximately 0·01 sec.) in the emission of the bulk of the fission neutrons. For this purpose we have used the intermittent neutron source described by Moon and others[3]. In this device, neutrons emitted by the intermittent bombardment of a target of heavy ice with deuterons are detected on a cathode ray oscillograph, the time-scale of which is interrupted by marks produced by the intermittent beam of ions. For the present experiment, the detecting chamber was shielded with cadmium and placed nearer the source (about 2 metres instead of 5 metres), thus increasing the intensity and diminishing the lag due to the time of flight of any slow neutrons present. The period of intermittence was 0·005 sec. and delays exceeding 0·001 sec. could have been detected. Delays larger than 0·005 sec. would have resulted in an approximately uniform distribution of the fission particles over the time-scale. Experiments were made by surrounding the source with a considerable thickness (approximately 10 cm.) of uranium oxide (U_3O_8). Check experiments were made without the uranium, and also without the source but with the uranium.

Two complete sets of experiments were made, one with the source surrounded with wax inside the uranium, the other with it bare. The second experiment showed a slight positive effect corresponding to a cross-section of about 5×10^{-26} cm., about that found by Roberts, but this is of the order of the experimental error. We can, however, say that the effect is less than corresponds to a cross-section of 10^{-25} cm., so that it is unlikely that the bulk of the emission is due to effects having a delay of more than 10^{-3} sec. in the case of the primary neutrons from the D—D process. The experiment with the wax gave a negative result, and assuming that the number of 'slow' neutrons emitted from the source, which was surrounded by about 5 cm. wax, is a quarter that of the fast neutrons emitted under the same conditions, we should have detected a cross-section for the production of a delayed neutron of 5×10^{-25} cm. The value given by Anderson and others for fission is 2×10^{-24} cm., and according to Szilard about two neutrons are produced per fission.

Evaluation of the Beta Upper Energy Limits with Simple Absorption Data

OF late, several methods have been suggested by different workers[1,2,3,4] for estimating the β upper energy limits of radio-elements (especially those produced in artificial disintegrations) from absorption measurements made with aluminium foils. One great drawback of these methods is that most of them are too empirical and without a theoretical basis, and are limited to cases of simple spectra.

A new method is now proposed, which enables one not only to obtain good results, but also to analyse complex spectra into simple ones, from the ordinary absorption data. It consists essentially in utilizing the absorption measurements to construct the Fermi and Konopinski-Uhlenbeck theoretical curves and deduce the upper limit by extrapolation.

As is well known, the Fermi and Konopinski-Uhlenbeck[5] curves have been used for magnetic spectrograph and cloud chamber data. Kurie, Richardson and Paxton[6] first pointed out a practical way of doing this, and many workers have applied it to several cases with success. To plot these curves, two quantities are required, namely, the number N of β-particles in successive small momentum (or energy) intervals, and the average momentum M (or average energy E) for each of those intervals, all along the distribution curve, chiefly in the high-energy portion. Certain simple considerations make it possible to derive these two factors N and M (or E) to a good approximation even from simple absorption measurements. In consequence, absorption data can be used to draw the Fermi and Konopinski-Uhlenbeck curves.

This new method has been applied with interesting results to radiorhodium and radiosilver obtained with slow neutron activation. The two periods of rhodium are supposed to be isomeric, while those of silver are not.

Method	Rhodium	
	45 sec.	4·2 min.
Konopinski-Uhlenbeck	2·70 ± 0·05 Mev.	2·75 ± 0·05 Mev.
Fermi	2·62 ± 0·05 „	2·66 ± 0 05 „

Method	Silver	
	24 sec	2 5 min
Konopinski-Uhlenbeck	2·81 ± 0·08 Mev.	1 72 ± 0·05 Mev.
Fermi	2·60 ± 0 10 „	1 67 ± 0·07 „

The following points are worth noting:

(1) The above values are in good agreement with those obtained by different methods[7].

(2) The upper energy limits of the two periods of rhodium are the same within the limits of experimental error, an important result which confirms Pontecorvo's simple scheme[8] for the isomers of rhodium.

(3) For rhodium, besides the above-mentioned two upper limits, a third one is obtained of about 3·8 Mev., which is found always linked with the 45 sec. period. A close comparative study of the curves of rhodium and silver clearly shows that this value cannot be referred to either of the isomeric periods. Various hypotheses, such as 'group' spectra, radioactive rhodium (102), secondary electrons, etc., have been tried to explain it.

The new method has the following advantages over others: (*a*) it has a theoretical basis, namely, Fermi's theory of β-disintegration; (*b*) it enables a complex spectrum to be split up into simple spectra; (*c*) measurements very close to the limiting thickness of absorber are not necessary; (*d*) it is impersonal and objective at the same time, since the upper limit is given by a definite point of intersection of the curve with the X-axis.

A New Method of Determining *e*/*m* for Medium High Velocities

CONSIDER the motion of an electron moving in an electric field between two charged co-axial cylinders. If the electrons are emitted from S (Fig. 1) with velocity v, they can be refocused at a point S' on the circle r_0 if

$$(1)\quad \Theta = \frac{\pi\gamma}{\sqrt{1+\gamma^2}} \text{ where } \gamma = \frac{1}{\sqrt{1-v^2/c^2}}\ ;$$

and further, if the field at the circle of radius r_0 satisfies the relation

$$(2)\quad eF = \frac{m_0\gamma v^2}{r_0}.$$

From (1) and (2) we get

$$(3)\quad \frac{e}{m_0} = \frac{c^2}{Fr_0}\sqrt{\frac{(2\Theta^2-\pi^2)^2}{(\pi^2-\Theta^2)\Theta^2}}\ \text{e.s.u.gm.}^{-1}.$$

Thus a simultaneous measurement of the two quantities Θ and F would give a value for e/m_0.

The method becomes much more convenient when a radioactive source is used at S emitting a continuous velocity spectrum of electrons. The angle Θ can then be fixed and it is only necessary to vary the field until a maximum of intensity is observed at S'. The best way of doing this in practice would appear to be to have just a slit at S' and to place the detecting counter at C, approximately a further angle Θ round the centre. This will always be possible, since Θ must lie between $\pi/\sqrt{2}$ and π.

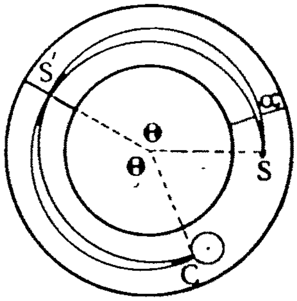

Fig. 1.

In effect, the choice of a definite angle Θ specifies the energy of the electrons for which e/m_0 is to be found:

$$(4)\quad E = \frac{m_0c^2}{e}\left(\sqrt{\frac{\Theta^2}{\pi^2-\Theta^2}}-1\right)300 \text{ ev.};$$

and so only one deflection measurement is necessary.

The increase of the angle of refocusing Θ with the velocity is a pure relativistic effect and also takes place in a Coulomb field, where the dependence of Θ on the velocity can be found readily from the precession of the ellipse, $\Theta = \pi\gamma$. Owing to the stronger focusing properties of the inverse r field, slow electrons are refocused in this field earlier than in a Coulomb field, and the increase of Θ with the velocity is slower.

The accuracy of the method will depend mainly on the determination of the angle Θ, since

$$(5)\quad \frac{d(e/m_0)}{e/m_0} = \frac{\pi^4}{(2\Theta^2-\pi^2)(\pi^2-\Theta^2)}\,\frac{d\Theta}{\Theta}\ ;$$

and this is very large both at small and high velocities. The error is a minimum for $v/c = \frac{1}{3}\sqrt{6} \doteq 0{\cdot}81$, corresponding to an energy of nearly 10^6 ev., which is certainly an interesting region. The angle Θ is then $\frac{\pi}{2}\sqrt{3} = 155{\cdot}88°$, and under this condition,

$$\frac{d(e/m_0)}{e/m_0} = 8\,\frac{d\Theta}{\Theta}$$

It does not seem at all impossible ultimately to have the angle Θ measured to 1 part in 10,000, which would lead to an accuracy of 1 in 1,000 for e/m_0. Using an apparatus with $r_0 = 25$ cm. and a gap between the two cylinders of 0·5 cm., 10,000 volts would be required to refocus electrons of this energy.

Apart from the question of measuring the voltage, the error in fixing the exact value of the field to give focusing is determined by the resolving power of the apparatus. If this is too high, other errors would be introduced due to lack of intensity. With a source of 1 mc. on a 0·1 mm. wire, ample intensity should be obtained with an angular spread of $\alpha = 2 \times 10^{-2}$ radians. With these values the uncertainty in dF/F should not exceed 10^{-4}.

Apart from the question whether an accuracy could in fact be realized comparable with that attained already for slower electrons, this method is interesting in so far as it is peculiarly adapted for use with the electrons or positrons forming the continuous spectrum from radioactive bodies.

An interesting analogy exists between this method and that developed by Henneberg[1], Bartky and Dempster[2] and Shaw[3]. They also use a field between two co-axial cylinders, but since their electrons are very slow, the angle of refocusing is practically $\pi/\sqrt{2}$ and quite insensitive to changes in velocity. An artificial precession is then introduced by a magnetic field parallel to the axis of the cylinders, when the method becomes formally similar to that described here.

Phosphatide Exchange between Plasma and Organs

THE blood plasma of rabbits contains about 80 mgm. phosphatides. What is the average time a phosphatide molecule spends in the plasma?

To answer this question we administered labelled sodium phosphate of an activity of 0·01 millicurie to rabbit *A*. The active phosphate was kindly presented us by Prof. Lawrence. After the lapse of a day the plasma contained phosphatides of an appreciable activity. We added this plasma to the corpuscles from rabbit *B* and reintroduced the blood obtained, composed of non-active corpuscles and active plasma, into the rabbit *B*. Blood samples were taken at intervals from the ear vein of rabbit *B* and the disappearance of the active phosphatides from the plasma was followed. As seen in Table 1, about one half of the labelled phosphatide molecules disappeared in the course of 1½ hours. To find what happened to the molecules which disappeared we killed the rabbit after 4 hours, extracted the phosphatides from the organs with ether-alcohol, determined the phosphatide phosphorus content of the extracts by the colorimetric method and their activity by making use of a Geiger counter. The results are seen in Table 1. Nearly one third of the labelled phosphatide molecules introduced into the plasma were after the lapse of four hours present in the liver; the muscles contained about 3 per cent, the other organs less. Though intestinal tract, bones and skin were not investigated, about 60 per cent of the labelled phosphatides introduced into the plasma could be recovered in the organs.

TABLE 1.

EXCHANGE OF LABELLED PHOSPHATIDES BETWEEN PLASMA AND ORGANS.
(Active inorganic P is only present in negligible amount).

	Lungs	6·0	1·13	1·14
	Kidneys	5·82	0·96	1·00
	Heart	6·5	0·23	0·20
	Brain	13·4	0·06	0·27

TABLE 2.

FORMATION OF LABELLED PHOSPHATIDES

Organ	Percentage of organ phosphatide synthesized in the course of 3½ hours (obtained by comparing the specific activities of the inorg. P and phosphatide P of the organs)
Plasma	0·7
Liver	7·4
Muscles	1·2
Lungs	2·9
Kidneys	4·8
Heart	1·6
Brain	0·9
Spleen	2·4
Intestinal mucosa	4·1
Stomach	10·0

Radioactive phosphorus as an indicator has been used in numerous cases[1] to determine the relative rate and the place of formation of phosphatide molecules. The line of attack described above differs, however, entirely from that pursued in the references given above. We are following the exchange of phosphatide molecules between the plasma and the organs and not their formation from components. How these two entirely different magnitudes compare is seen in Tables 1 and 2. During the period in which 7 per cent of all the phosphatide molecules present in the liver are renewed by synthesis, 5 per cent of the phosphatide molecules of the liver are replaced by phosphatide molecules previously present in the plasma. The amount of newly synthesized phosphatides present, for example in the liver, was determined by comparing the specific activity of the liver phosphatide phosphorus with that of the liver inorganic phosphorus in experiments in which labelled sodium phosphate was injected into the vein of a rabbit drop by drop. The amount of labelled phosphatide synthesized from labelled inorganic phosphate and other components in the course of the exchange experiment can be entirely disregarded. Due to the intense interaction of the plasma phosphate with that of the organs, the amount of active inorganic phosphorus present in the plasma of rabbit *A* was only one third of that of the active phosphatide phosphorus at the end of the twenty-four hours. This ratio was further shifted in favour of the phosphatide phosphorus after injecting the plasma into rabbit *B*; 10 minutes later it was 1/50, and four hours later 1/150.

As seen in Tables 1 and 2, liver, in which a high phosphatide turnover takes place, exchanges easily its phosphatide molecules with those present in the plasma, while muscles, in which phosphatides are synthesized slowly, also exchange phosphatide molecules at a very slow rate. The kidneys show a different behaviour. There is a fast new-formation of phosphatides, while the rate at which the phosphatide molecules are carried into the plasma is slow.

Though the individual phosphatide molecules, as seen above, leave the plasma at a fairly fast rate, the speed with which they penetrate the walls of the capillaries and reach the lymph is much smaller than in the case of electrolytes. We introduced 1 c.c. plasma containing labelled sodium chloride into a rabbit; after the lapse of a few minutes we found the labelled sodium chloride to be diluted 590 times, showing that the labelled sodium is now distributed in 590 c.c. fluid. We carried out similar experiments with plasma containing labelled phosphatides and after the lapse of ten minutes found a dilution, in rabbits weighing 2·3–2·4 kgm. of 105–130. The phosphatides are, thus, distributed in a volume of

105–130 c.c. liquid, which is not very appreciably more than the total plasma volume. The latter amounts, in the case of a rabbit weighing 2·3 kgm., to about 90 c.c.

All data given in this note relate to those phosphatide molecules which are soluble in petrol ether. We found great differences in the turnover of the different types of phosphatides and this induced us to carry out similar experiments as described above with each of the different types.

Preparation of Thyroxine from Casein treated with Iodine

In a recent paper by Ludwig and Mutzenbecher[1] experiments are described in which treatment of casein with iodine under carefully defined conditions is stated to yield a physiologically active product from which thyroxine can be isolated.

In view of the existing knowledge of the chemistry of thyroxine, these results are so surprising that it appeared to us to be desirable to repeat the experiments. We have therefore carried out three preparations under the conditions laid down by the German workers and we have confirmed the findings of the latter in every respect.

The casein employed in our experiments was a commercial preparation (B.D.H. acetic-precipitated, soluble). Three separate lots of 100 gm. of this material gave, under Ludwig and Mutzenbecher's conditions of iodination, products containing 7·7, 7·7 and 8·7 per cent of iodine respectively; a physiological test on one of these products indicated an activity (as measured by the effect on the basal metabolic rate of the rat) of the order of 1/300 of that of thyroxine.

Hydrolysis of the iodinated casein preparations with barium hydroxide as described by the German workers led to iodine-rich fractions, containing 37–45 per cent iodine, solutions of which in 0·1 *N* sodium carbonate solution slowly deposited small amounts of a crystalline sodium salt; the latter could be converted in the usual manner into a compound indistinguishable in chemical properties from thyroxine and showing the full physiological activity of the latter; the chemical identification was completed by the catalytic deiodination of the product isolated to give a characteristic preparation of thyronine. The yields of crystalline thyroxine which we have isolated have been of the order of 100 mgm. from 100 gm. of iodinated casein.

There seems, therefore, to be no doubt as to the correctness of the results obtained by Ludwig and Mutzenbecher, and it becomes a matter of great interest to consider the possible mechanisms by which the formation of thyroxine in these experiments may be brought about.

The first point which seems to us to be significant is that the conditions employed by Ludwig and Mutzenbecher for the iodination of the casein, and which according to them must be closely observed, are not such as to bring about maximum substitution of iodine in the casein molecule but are rather such as to favour the oxidizing action of iodine. Now the hypothesis has been previously advanced by one of us that the biological synthesis of thyroxine may occur from tyrosine through the stage of diiodotyrosine, two molecules of which may undergo oxidative coupling with elimination of one side-chain; it has been supposed that an enzymic mechanism may exist in the thyroid gland by means of which this reaction could be brought about. In the experiments of Ludwig and Mutzenbecher the participation of oxidizing enzymes which might be present in the casein preparation could not be completely excluded owing to the conditions of the iodination (maintenance for about four hours at 37° and *p*H 8·5); we have found, however, that initial boiling of the casein in aqueous suspension does not affect the result, so that enzymic action cannot be involved.

There appear, therefore, to be two possibilities remaining: (1) iodine itself, under the conditions employed, may be able to effect the oxidative coupling of two molecules of diiodotyrosine which is postulated as a stage in the biogenesis of thyroxine; (2) casein may contain preformed thyronine as one of its constituent amino-acids and this may be iodinated to thyroxine.

The first of these explanations is favoured by Ludwig and Mutzenbecher; the difficulties in the way of its acceptance are (*a*) the inherent unlikelihood that iodine should bring about such a drastic oxidation and (*b*) the still greater improbability that a reaction of the type required should occur between two tyrosine residues within the protein molecule. On the other hand, although the presence of a small amount of thyronine in casein (and indeed in other tyrosine-containing proteins) might well have escaped detection hitherto, all attempts which have been made in the past to convert thyronine into thyroxine have failed.

We are at present engaged in experiments which it is hoped may throw further light on the chemical basis of the very interesting phenomena which the work of Ludwig and Mutzenbecher has revealed.

The Cromer Forest Bed Implements

Researches I have carried out recently, by means of grants from the Royal Society, relating to the artefacts found in the basal layer of the Cromer Forest Bed, have shown that some six periods of flaking are recognizable on these specimens. I conclude, therefore, that the deposit containing them is composed, in part, of the wreckage of a land surface, or surfaces, on which the makers of the flint implements lived prior to the laying down of the Forest Bed. The various groups of artefacts from the base of this deposit differ not only in their patination and condition, but also, it seems, in their forms and flaking. One of the assemblages of specimens referable, apparently, to the earlier part of the Cromer Forest Bed, is that composed of the well-known ochreous-yellow implements, and flakes found upon the foreshore site at Cromer.

Since 1919, I have made periodical examinations of the large spreads of flint, exposed at low tide, along the shore from Sheringham to Mundesley, and it is beyond dispute that it is only at Cromer that the ochreous specimens are, or rather were, present in any quantity. They are exceedingly rare at Sheringham, West and East Runton, while to the south-east of Cromer, though stone beds are present upon the foreshore, no ochreous artefacts, so far as I have been able to observe, occur at these sites. These facts are of considerable significance when the question of the origin of the flaking of the ochreous specimens comes up for consideration. For example, they make it very difficult to believe that wave-action has been responsible for this flaking, as, apart from the lack of evidence that such action could produce the required effect, it is incredible that it would be confined, to all intents and purposes, to only one spot on the north-east coast of Norfolk. Moreover, the ochreous artefacts are not made from the flint which is being eroded from the chalk on the foreshore, but from another variety; while the ever-lessening number of the ochreous specimens on the Cromer site—a reduction brought about by their removal by archæologists and others—indicates that these flints are not being produced at the present time.

As is known, the ochreous artefacts generally exhibit a thick and ancient patination, while the flakes very often show flat striking platforms, prominent cones and bulbs of percussion and the usual characteristics of human workmanship.

Reduction of the Ctenidia in the Lamellibranchia

The ctenidia of a typical lamellibranch are each composed of two demibranchs arranged one on each side of the ctenidial axis. In three families, however, the Lucinidæ, the Montacutidæ and the Teredinidæ, the ctenidium is composed of one demibranch only. A list of such lamellibranchs found in British waters is given by Atkins[1], type G. It is reproduced below.

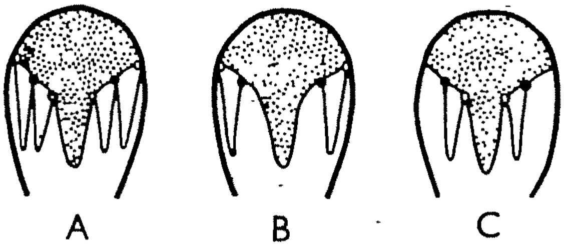
Lucinidæ.
  Myrtea (Lucina) spinifera.
  Phacoides (Lucina) borealis.
Montacutidæ.
  Montacuta ferruginosa.
  Montacuta substriata.
  Mysella (Montacuta) bidentata
Teredinidæ.
  Teredo norvegica.
  Teredo navalis.
  Teredo megotara.
  **Xylophaga dorsalis.*

A similar condition obtains in the American genus *Bankia*, as shown by Sigerfoos[2] who examined *B.* (*Xylotrya*) *gouldi*.

It has generally been assumed, on little definite evidence, that in all these cases it is the outer demibranch which has been lost[1,2,3,4]. The question can only be definitely decided by determining the positions of the afferent and efferent branchial veins. The afferent vein invariably runs in the ctenidial axis. It receives blood from the kidney and passes it down the descending lamellæ of the ctenidium. The typical lamellibranch possesses two pairs of efferent veins which run along the dorsal margins of the ascending lamellæ of each ctenidium. They convey blood from the ctenidia to the auricles. This normal arrangement is indicated in *A*.

Where one demibranch has been lost, the relative positions of the afferent and efferent branchial veins remain unchanged (*B*, *C*). By the examination of serial sections it is possible to trace the connexion between the afferent vein and the kidney, or between the efferent vein and the auricle, and thus (by identifying the veins) to determine the position of the ctenidial axis.

Menegaux[3] discusses the position of the afferent and efferent veins in *Lucina*, and his description leaves no doubt that in the Lucinidæ the single demibranch is the *outer* one (*B*).



Diagrammatic transverse sections to show reduction of the ctenidia in certain lamellibranchs. A, typical lamellibranch. B, Lucinidæ and Teredinidæ. C, Montacutidæ.
The afferent branchial vein at the ctenidial axis is figured black, and the efferent branchial veins at the dorsal borders of the ascending lamellæ are figured white.

In the Montacutidæ, I have been able to examine one species only, *Montacuta ferruginosa*, in which it is clear that it is the *inner* demibranch which is retained (*C*). This is in accordance with the views of Miss M. L. Popham, who has sectioned all the species of the Montacutidæ found in British waters.

Examination of the illustrations of *Teredo* and *Bankia* given by Ridewood[4] and Sigerfoos[2] respectively make it abundantly clear that in these genera it is the *outer* demibranch which is retained. My own investigations on *Xylophaga dorsalis* establish that a similar condition obtains in this species.

In the Lucinidæ and Teredinidæ, therefore, the ctenidium is composed of the *outer* demibranch only; whereas in the Montacutidæ the single demibranch is the *inner* one.

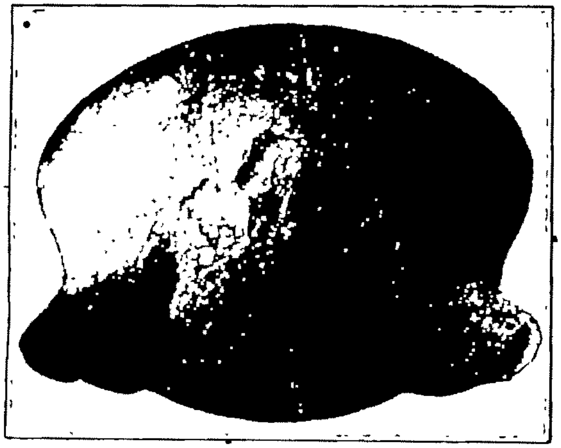
Cranidial Muscle Scars of '*Illænus*' *proles* var. *shelvensis* Whittard

From the core of the Walsall boring[1] which was put down in 1935, Dr. and Mrs. A. J. Butler collected a large number of Silurian fossils. Among those from the Purple Shales of the Upper Llandovery there are internal casts of two trilobite middle-shields referable respectively to *Phacops* (*Portlockia*) *elegans* Sars and Boeck, obtained at a depth of 1,050–1,055 feet, and to '*Illænus*' *proles* var. *shelvensis* Whittard, from 982–987 feet down. The illænid, as shown in the accompanying figure, though rather larger than the individuals upon which Prof. Whittard founded the variety[2], differs from these only in the remarkable preservation of the impressions of what seem to be muscular platforms. The pair of these which occur at the front of the glabella are expanded anteriorly, and are covered with small depressions like those occurring at points of muscular attachment in modern Crustacea. About 0·6 mm. behind these well-marked muscular platforms under the posterior part of the glabella we find another pair that are poorly defined with small raised areas sometimes isolated, irregularly arranged, and not so high as those in front.



INTERNAL CAST OF MIDDLE-SHIELD OF "*Illænus*" *proles* VAR. *shelvensis* WHITTARD, SHOWING IMPRESSIONS OF PAIRED MUSCLE-PLATFORMS UNDER FRONT PART OF GLABELLA, WITH A PAIR OF FAINTER AND LESS REGULAR MUSCULAR AREAS BEHIND. ×1¾.

Birmingham University Geological Museum, Figured Collection T. 215.

In cranidia areas of muscular insertion have been previously described by von Volborth and Prof. Öpik. In his *Illænus crassicauda* var. *dalmanni*, von Volborth[3] found four paired areas under the glabella —the illustration is copied by Salter[4]—and clearly distinguished these from a pair of elongate oval depressions in the axial furrows. None of von Volborth's scars, we note, is relatively as large as the front pair in '*I.*' *proles* var. *shelvensis*. Under the frontal lobe of the glabella of several species of *Chasmops* Öpik[5] has discovered small elevations in two rows converging in front and behind, which he regards as points of attachment for the muscles which served to dilate the œsophagus.

In explaining the novel musculature of '*Illænus*' *proles* var. *shelvensis*, the easiest supposition is that it may have arisen through fusion of muscle impressions like those seen in *I. crassicauda* var. *dalmanni*, probably three pairs going to the making of the large anterior muscle scars of the Walsall form. This development may have been connected with change in feeding habits, for example, evolution of a sucking mouth, as it is unlikely that an enlarged pair of mandibular appendages ever appeared in the Illænidæ.

The genotype of Illænus is *I. crassicauda* (Wahlenberg). Von Volborth's variety certainly seems to come close to this. It would, therefore, be justifiable at once to separate '*I.*' *proles* var. *shelvensis* as the representative of a new genus. It has been thought better, however, to delay placing the Shelve and Walsall specimens in a new systematic position, since re-examination of collections of illænids may in the near future give additional information about the condition of cranidial muscle platforms and the possible value of these features in taxonomy.

'Auto-parasitism' by *Nemeritis canescens* (Grav.) (Ichneumonidæ)

THERE appears to be no published record of oviposition by an insect in the body of another of its own species. This interesting phenomenon, however, occurs in *Nemeritis canescens* (Grav.) (Hymenoptera: Ichneumonidæ), a parasite of the Mediterranean flour moth (*Ephestia kühniella* Zeller) in certain circumstances.

Nemeritis canescens breeds parthenogenetically and is ready to oviposit within half an hour after its emergence from the pupa. In a jar containing fully grown host larvæ, the parasites which develop from them do not emerge simultaneously. Those that emerge first try to oviposit in those that will emerge in a day or two. The parasite succeeds in laying one or more eggs if its ovipositor pierces the soft ventral side of the abdomen of the imprisoned parasite in the silken cocoon. The egg hatches into a larva which undergoes a part of its development in the abdomen of its host, which, nevertheless, develops into an imago and may live for some days afterwards.

Experiments corroborated the above observations. Two parasites were released for six hours in a small jar containing about forty advanced parasite pupæ from which the imagines were expected to emerge in a day or two. As each imago emerged, it was at once transferred to a tube and fed on sucrose solution until it died. Twenty-five such parasites were fed in this way, and inside the abdomen of two of them partly developed parasitic larvæ were found. They were both dead.

In cultures where 80–100 parasites are reared in a jar the percentage is found to be much higher. For batches of 10–20 parasites emerge at intervals of 12–24 hours, and when two batches of about forty parasites have emerged the chance of some of these successfully ovipositing in those that are yet to emerge is high.

Another interesting fact observed was that in Ephestia larvæ, where superparasitism by *Nemeritis* is a common occurrence, all parasitic larvæ in one host, except one, die in the first instar. Nevertheless, in the abdomen of an adult parasite that was dissected two larvæ were found, one well advanced in the third instar and the other in the second instar.

Pure Ethyl Alcohol for Absorption Spectrophotometry

ETHYL alcohol which has been dehydrated by an azeotropic process is liable to contain traces of absorbent impurities, for example, benzene[1], which make it more difficult to purify for absorption spectrophotometry. Alcohol known to have been produced by one of the above methods was subjected to the following processes:

(1) To each litre of alcohol 20 c.c. of water and 4 c.c. of sulphuric acid were added and the mixture refluxed for 2–3 hours, after which it was distilled, rejecting the first and last 10 per cent.

(2) 1·5 gm. of silver nitrate was dissolved in the minimum quantity of water and added to the alcohol in a tall vessel. To this was then added drop by drop and without shaking a solution of 3 gm. potassium hydroxide in 10–15 c.c. alcohol. This allows the silver oxide to precipitate in a finely divided form, and the vessel is left until all the precipitate has settled. The silver oxide is either filtered off or the liquid decanted and distilled, rejecting the first and last fractions as before[2].

(3) To remove the water, the alcohol was refluxed with calcium oxide in an atmosphere of nitrogen, the oxide itself having been prepared in an atmosphere of nitrogen.

(4) The purification was completed by distilling the product from (3) in an atmosphere of nitrogen.

Of the various methods which have been suggested for the purification of ethyl alcohol, the above sequence was found to be the most satisfactory, each step extending the transmission farther into the ultra-violet, the absorption curve for the final product being almost identical with that found by Harris[3] and superior to that found by Leighton, Crary, and Schipp[4] and Bielecki and Henri[5]. A final distillation from aluminium amalgam did not increase the transmission in the ultra-violet.

Points from Foregoing Letters

N. Bohr, R. Peierls and G. Placzek discuss the typical difference between nuclear reactions in the regions of discrete and continuous level distributions of the compound nucleus. The argument developed is used to clear up an apparent difficulty as regards the order of magnitude of the cross-sections of heavy nuclei for the photo-effect with ejection of neutrons.

La. Goldstein, A. Rogozinski and R. J. Walen have studied the diffusion of fast neutrons by uranium nuclei and the possibility of showing the emission of neutrons when this nucleus explodes. The sum of the cross-sections for elastic and inelastic scattering and for fission found implies that a chain reaction of fission, if such chain is possible, may be observed in a smaller mass than was hitherto thought necessary.

D. F. Gibbs and G. P. Thomson describe experiments with an intermittent source which show that the majority of the neutrons produced in the fission of uranium appear with a delay of less than 10^{-3} sec.

J. B. R. Rajam, P. C. Capron and M. de Hemptinne describe a method of determining the beta upper energy limits of radio-elements. The ordinary absorption data are used to construct the Fermi and Konopinski-Uhlenbeck curves, from which the upper limit is deduced by extrapolation. Results are given for radio-rhodium and radio-silver.

J. Aharoni suggests a new method for determining e/m for electrons of about a million volts energy. It is particularly applicable to electrons and positrons forming the continuous spectrum from radioactive bodies.

The exchange of phosphatide molecules between plasma and organs is compared by L. Hahn and G. Hevesy with the turnover of phosphatides in the latter.

C. R. Harington and R. V. Pitt Rivers report experiments confirming the recent observation of Ludwig and Mutzenbecher that treatment of casein with iodine under carefully controlled conditions yields a product which has physiological activity similar to that of thyroglobulin and from which thyroxine can be isolated. The mechanism of the formation of thyroxine under these conditions is discussed.

Some six periods of flaking have been recognized by J. Reid Moir upon the artefacts from the basal layer of the Cromer Forest Bed. One of the assemblages of specimens referred to is composed of the well-known yellow implements and flakes found upon the foreshore site at Cromer. The conditions existing at this site make it improbable that these specimens have been flaked by wave action.

R. D. Purchon states that in three families of Lamellibranchia the ctenidia are reduced to one demibranch on each side. This has always been assumed to be the inner one. By determining the position of the afferent and efferent veins, the former always running through the axis, it has been shown that in the Lucinidæ and Teredinidæ the inner demibranch has been lost; only in the Montacutidæ has the outer one been lost.

A. Lamont records an unexpected reduction in the number of cranidial muscle-scars in '*Illænus*' *proles* var. *shelvensis*, and points to the possible use of these features in the systematic subdivision of a difficult family.

An interesting phenomenon of one insect ovipositing in the body of another of its own species was observed in *Nemeritis canescens* (Grav.), by E. S. Narayanan. In Ephestia larvæ superparasitism by Nemeritis is a common occurrence, but all except one die in the first instar. In the abdomen of an adult parasite two larvæ were found, one in the third instar and the other in the second instar.

RESEARCH ITEMS

Artificial Parthenogenesis and Chromosome Constitution

An extensive study of the effects of artificial parthenogenesis upon the chromosome constitution of the cells resulting from the subsequent cleavages in the eggs of the frog *Rana nigromaculata* is reported by T. Kawamura (*J. Sci. Hirosima Univ.*, Series B, 1939). In most instances the successive cleavages occurred at the normal times, but in about 18 per cent they were delayed. The histories of 1,073 eggs were followed and in 413 that lived longer than seven days the chromosome number was determined; 49 per cent of these were haploid, 21 per cent were diploid, 23 per cent were triploid. The remainder were divided among tetraploid, hexaploid, hyperploid, haploid-diploid, haploid-triploid, haploid-pentaploid and triploid-hexaploid. In each instance an attempt is made to explain how the particular condition originated. The most viable type is the diploid. Some of the external characters of the parthenogenetic larvæ are described. The paper is provided with numerous tables and illustrations of the various chromosome conditions.

Properties of Renin

O. M. Helmer and I. H. Page (*J. Biol. Chem.*, **127**, 757; 1939) describe a method for purification of renin, a pressor substance from the renal cortex first described and so named by Tigerstedt and Bergman in 1898. The purest preparations raised arterial blood pressure 30 mm. mercury in dogs when injected in amounts representing 0·027 mgm. of nitrogen per kilo of body weight. In cats it was three times as active; 0·009 mgm. of nitrogen-containing extract produced the same rise. Colour tests for guanidin groups and for pentose were found to be especially strong in renin solutions, while those for adrenin were negative. Crystalline precipitates were formed on addition of flavianic acid or picric acid to hydrolysates of renin. The pressor action of renin in cats and dogs was not abolished by ergotamine or potentiated by cocaine, as is adrenin. Cats anæsthetized with pentobarbital supply suitable preparations for assay purposes.

Origin of Dahlia Varieties

A paper by A. J. Cobb (*J. Roy. Hort. Soc.*, **64**, Pt. 5, May 1939) gives a clear description of the origins of several types of garden dahlias. Vicente Cervantes, director of the Mexico Botanical Gardens, sent seeds and roots of *Dahlia pinnata* to Madrid, for the Abbé Cavanilles, in 1785, though the plant had been known in Mexico as early as 1575. *D. coccinea* and *D. rosea* were also described by Cavanilles in 1791. These three species were the parents of all the garden and show varieties until the appearance of the cactus dahlia. This last type was introduced by Henry Cannell in 1879, and was named *D. Juarezii*. Still another form, *D. Merckii*, was used as a parent in 1903, and thereby the forms with dark central disks and light ray florets were brought within horticultural practice. The dwarf 'Coltness Gems' are selections from progeny of this stock crossed with other garden varieties. The paper under review also gives detailed accounts of the practical cultivation of dahlias.

Triploid Red Alga

Kathleen M. Drew (*Ann. Bot.*, N.S., **3**, 347–368; 1939) has studied populations of *Plumaria elegans*. Plants bearing sexual organs have 31 chromosomes and plants bearing tetrasporangia have 62 chromosomes. A cystocarp results from fertilization, and reduction division takes place in the tetrasporangium. In addition, several plants bearing parasporangia and an occasional tetrasporangium had 93 chromosomes. These triploids form triploid paraspores. The development of the parasporangia is shown to be distinct from that of tetrasporangia, and the relationship between the triploid plants and the diplobiontic life-history of the species is as yet unknown.

Fruit Flies of China

We have received a copy of *Sinensia* (Contributions from the National Institute of Zoology and Botany, Academia Sinica, vol. 8, No. 2, April 1937). This journal is a bi-monthly publication and each volume comprises six parts with a total of 500–800 pages. It is to be obtained from the director of the Institute, 68 Ching Hsien Street, Nanking, price 6 dollars (Chinese) for foreign subscribers. The present issue is largely occupied by an important paper on the Trypetidæ or fruit flies of China, by Y. Zia, (pp. 103–226). Altogether 101 species are recognized, including one genus and 16 species that are described as new. This memoir is of special interest to workers on oriental Diptera and is a carefully executed and well-illustrated contribution. The remainder of the present issue of the journal is occupied by a paper entitled "Additional Fungi from China", (6), by S. C. Teng and S. H. Ou (pp. 227–297).

Fruit Breeding in the U.S.A.

The *American Fruit Grower* of March contains articles on the breeding of new varieties of fruits. M. A. Blake summarizes some of the results of the breeding programme started at the New Jersey experiment station in 1914 to determine facts about the inheritance of characters in the peach and to develop varieties of higher quality than those existing at the time. It takes at least five or six years to make a cross and obtain the first good crop of fruit. The following facts have been established during the past twenty-five years. When a variety with pure white-fleshed fruit was crossed with another white-fleshed variety, the progeny all gave pure white-fleshed fruit. Crosses between two heterozygous white-fleshed varieties gave progeny 75 per cent of which gave white-fleshed and 25 per cent yellow-fleshed fruit. A variety with pure white-fleshed fruit crossed with a yellow-fleshed variety gave an all white F_1 generation. Red flesh around the pit was found to be dominant over absence of red, whilst heavy pubescence was dominant over light or absence of pubescence. Small size of fruit was dominant over large. J. C. Miller contributes an article on strawberry breeding at the Louisiana experiment station. The variety Klondike accounts for 95 per cent of the total plantings in this area. Breeding experiments aim at raising varieties sweeter than Klondike, but with the same shipping qualities and resistant to leaf spot (*Mycosphærella fragariæ*) and scorch (*Diplocarpon earliana*). Crosses have been made between varieties which show any resistance to these diseases. The resulting fruit is fermented to free the seeds, which are then dried and cold-stored until December. They are germinated in a greenhouse and the best plants planted outdoors in May; 20 to 40 of the 250 to 600 plants produced by each seedling are transplanted and sprayed every ten days with spore suspensions of the leaf spot and scorch diseases. All except 2–5 per cent of the seedlings are eliminated in the first year, the remainder being studied further for yield and quality.

Lime Sulphur Injury

LIME sulphur has been used as a fungicide for more than a hundred years and is still the most effective agent known for the control of apple scab. In certain conditions, however, it causes considerable damage to foliage and fruit. Scorching of the leaves and shedding of fruit are the most obvious symptoms, but recent work (summarized by Norman F. Childers, *American Fruit Grower*, April) has shown that less obvious but equally serious damage may result. Trunk growth of trees sprayed with lime sulphur may be much reduced, and reductions in the leaf growth of apples and cherries have been demonstrated. Heinicke and Hoffmann have recently shown that spraying may seriously reduce the rate of photosynthesis, especially at high temperatures. These reductions persisted for seven days or longer, with no apparent external injury to the leaves. Preparations of elementary sulphur are generally much less damaging in this respect, but on the other hand are less effective against bad attacks of scab.

The Smut Fungi

PROGRESS of knowledge about the life-cycles of the smut fungi has gradually revealed a bewildering though fascinating variety, which Miss Kathleen Sampson described in her presidential address to the British Mycological Society (*Trans. Brit. Mycol. Soc.*, 23, No. 1, 1–23, May 1939). The Ustilaginales show a general similarity of life-history to the larger Hymenomycetes, but each species appears to have its own characteristics. Fusions of nuclei appear at different stages, but are often associated with the young chlamydospore. Meiosis often follows close after fertilization. Heterothallism is common but is occasionally a complex organization, with four factors instead of two. Smut fungi appear readily to adopt a saprophytic mode of life, a fact which should not be forgotten when economic measures of control are being planned. The plus and minus strains of simple heterothallic forms can often be separated by growth upon selective media. Genetic implications of heterothallism are also discussed, whilst the frequency of specific hybrids and the ever-increasing number of physiological forms raise considerable anxiety as to the validity of species concepts. An examination of the available evidence leads Miss Sampson to the conclusion that the parasitic mycelium of smut fungi has two types of nuclei associated in a loose partnership which is more typical of the Hymenomycetes than the Uredinales. The paper provides a wealth of information for the teacher in mycology, and is an authoritative stocktaking of extant knowledge about a very difficult group of fungi.

A Fungus upon the Liverwort *Riccia Himalayensis*

LIVERWORTS are occasionally attacked by fungi. The Jungermanniales provide the most numerou hosts but an increasing number of the Marchantiales are now known to be subject to fungal attack K. S. Srinivasan has recently described a furthe parasite on *Riccia himalayensis*, a liverwort growing in Madras (*Trans. Brit. Mycol. Soc.*, 23, No. 1, 55–62 May 1939). The fungus is *Phærosphærella Riccia* and it appears to be limited to the gametophyte stage of its host. Spermogonia and perithecia are formed with numerous asci, but the oogonia are non-functional and rapidly disintegrate. The spermogonia liberate spermatia which, however, are of no use by themselves. Asci are produced from ordinary vegetative hyphæ. Sclerotia are formed in the liverwort thallus and serve to perpetuate the fungus from year to year

Movement of Water in the Soil

IN his presidential address to the Royal Meteorological Society, B. A. Keen gave an account of how a theory of the movement of water in the soil that has long been generally accepted, and which provides a simple and plausible explanation of certain traditional cultivation practices such as rolling, harrowing and hoeing, has had to be abandoned in recent years and to be replaced by a new theory developed and experimentally verified mainly by Haines and Schofield (*Quart. J. Roy. Meteor. Soc.*, April 1939.) The old theory is the capillary theory of soil water movement according to which the rain that percolates to some depth into the soil forms a reservoir that can be drawn on by plants in drought, the water ascending by capillary tubes, built up from the spaces between the soil particles, from saturated levels many feet below the surface to supply the roots of the plants at higher levels. According to this theory, harrowing and hoeing conserve moisture by destroying the top few inches of the capillary tubes and so checking evaporation from the surface, while rolling crops in spring reverses the process by diminishing the space between soil particles near the surface and so allowing the capillary tubes to bring water to the upper layers of the soil. It was found at Rothamsted from observations on the water level in cylinders closed at the bottom and filled with various soils, the top being kept free of weeds, that capillary rise actually does not exceed 3 or 4 feet even in such a drought as that of 1921. Haines showed, moreover, that the pore space in soil is essentially cellular, not capillary, and that with both increasing and decreasing moisture content the movement of water takes place through sudden changes corresponding with the abrupt emptying and filling of the cells. Schofield investigated the marked hysteresis in moisture content according as the soil is being moistened or dried. Under the new theory, it may be noted, the value of cultivation lies in the encouragement of soil crumb formation, while its control of soil moisture is confined to the removal of weeds that are competing for moisture and nutriment.

The Central Core of the Earth

Gutenberg and Richter, in their fourth paper "on seismic waves" (*Gerlands Beiträge zur Geophysik*, 54, 94–136; 1939) revise the travel times and velocities of such waves as have been given previously by them, using for the purpose observational data from deep focus earthquakes. The new tables contain calculated travel times for zero focal depth for the important phases of earthquake waves, and a re-interpretation of the observations of the waves *P′* and *SKS*. In this connexion the authors give a diagram showing the passage of longitudinal waves through the earth's core and exhibiting the refraction which, from their observations, appears to amount almost to total reflection for a wave approaching an inner core. A table is also given of the velocities of seismic waves and the calculated elastic constants of the materials through which the waves pass, all given as functions of the depth within the earth.

Preparation of *l*-Tartaric Acid

THE resolution of the mirror-image hemihedral crystals of sodium ammonium tartrate by Pasteur is the classical example of the resolution of racemic tartaric acid. Later, Pasteur observed that the mould *Penicillium glaucum* would consume ammonium *d*-tartrate from a solution of the racemate, thus effecting a preparation of ammonium *l*-tartrate. The third method of Pasteur was by salt formation with an optically active base, cinchonine. The latter was the only method of practical significance and was the usual procedure for the preparation of *l*-tartaric acid. The procedure is tedious and the yield poor. W. T. Haskins and C. S. Hudson (*J. Amer. Chem. Soc.*, 61, 1266; 1939) have now described an improved method of obtaining *l*-tartaric acid which gives an overall yield of more than 90 per cent. It depends on the resolution of racemic acid with 2[*d*-gluco-*d*-gulo-hexahydroxyl]-benzimidazole. In the same paper a new method of preparation of benzimidazoles substituted in the [2] position with sugar residues is described which is based on the reaction of aldonic acids or lactones with *o*-phenylenediamine, and the properties of a number of these substituted benzimidazoles are described. In the resolution, the racemic acid and base were dissolved in hot water, alcohol was added, and crystallization induced by scratching. The crystalline acid-*l*-tartrate salt which separated was washed with alcohol and could be recrystallized with negligible loss. The *l*-tartaric acid was obtained by precipitating the base with ammonia, precipitating the acid in the filtrate as the lead salt, and decomposing this with hydrogen sulphide.

Electrical Interference

WE have received from the British Thomson-Houston Company, Ltd., a pamphlet containing two papers by T. H. Kinman of its research laboratory entitled "Radio Interference Measurements" and "Electrical Interference in Flying" respectively. Considerable progress has now been made in producing 'radio-interference-free' electrical appliances, and in many cases troublesome 'interference' with radio can be very satisfactorily suppressed. The British Standards Institution now issues to manufacturers a special mark which they can stamp on their radio apparatus when it satisfies the limits of the disturbance tolerated in the B.S.I. specification. Measurements are at present mainly limited to the medium and long-wave broadcast frequencies between 1,500 and 200 kilocycles. In aeroplanes which have radio communication with the earth, great pains are taken to prevent interference produced by the ignition apparatus on board by waves of almost any frequency. In some aeroplanes, particularly those owned privately, where no devices for suppression are employed, the interference they produce with the radio apparatus of other aircraft or of television sets on the ground is very serious. If this aeroplane move parallel to other aeroplanes, it may cause danger as well as annoyance to them by preventing them from landing during fogs, etc. The low audible frequency which is heard after rectification in the receiver is characteristic of spark frequency and can be used to distinguish whether it comes from a magneto or a motor.

Catalogue of Double Star Orbits

A CATALOGUE of orbits for visual binaries is published from the Lund Observatory, Sweden, by B. Ekenberg. It supplements a preceding catalogue by Luplau Janssen, Fjeltofte and Lauritzen, who gave a list of all orbits computed up to 1926. Other catalogues by Finsen and by Baize have been published, but these usually select the best derived orbit for each pair. The catalogues from Lund give all computed orbits for any one star, and such a list will be found very useful by double-star observers and computers. The two Lund compilations contain 1051 orbits relating to some 197 systems. (The number of other pairs in which orbital motion, often very slow, is observable exceeds 1,500.) In addition, there are more than fifty orbits received after the printing of the Catalogue and given in an appendix. Among the interesting re-computed orbits included in the present list are: (1) γ Andromedæ BC with a period of from 55 to 56 years and a high eccentricity of 0·83 or 0·92 according to two separate computers. The present apparent separation of the component stars is about 0·43″. (2) α Centauri with a period of 80 years and eccentricity of orbit 0·52. (3) The spectroscopic binary *Aa*, comprising the brighter star of the well-known binary, ζ Ursæ Majoris (Mizar), with a period of 20·5305 days and eccentricity of orbit 0·53. The observations giving this orbit were made at Mt. Wilson with the 20-foot interferometer attached to the 100-inch reflector, the observed separation of the components being of the order 0·01″.

A Simple Wedge-Photometer

H. W. NEWTON has recently published a paper describing a simple wedge-photometer for observing bright chromospheric eruptions with a spectrohelioscope (*Mon. Not. Roy. Astro. Soc.*, 99, 5, March 1939). Within recent times there has been established a relationship between bright chromospheric eruptions and sudden ionic disturbances, and it has become necessary to obtain further data concerning the intensity of the solar eruptions. The simple wedge-photometer, described in the paper, is intended to make rapid measurements of the intensities of bright chromospheric eruptions observed with a spectrohelioscope. A secondary line shifter half the height of the primary one enables a comparison of the peak intensity of a flocculus to be made directly with the adjacent continuous spectrum. Each instrument requires certain corrections on account of its finite resolving power and also for scattered light. Uncorrected observations of bright eruptions will provide the order of magnitude and the time-intensity curve for any particular eruption. The instrument will fulfil its purpose—to make rapid observations in conditions where the phenomena under investigation are varying very quickly, and where speed rather than great accuracy is required.

RECENT EXPERIMENTAL RESULTS IN NUCLEAR ISOMERISM

By DR. B. PONTECORVO, LABORATORY OF NUCLEAR CHEMISTRY, COLLÈGE DE FRANCE, PARIS

THE hypothesis that two atomic nuclei indistinguishable in respect of atomic and mass number could nevertheless have different radioactive properties (the hypothesis of nuclear isomerism) was put forward for the first time by Soddy[1] in 1917. In 1921 uranium Z was discovered by Hahn[2]; by studying the chemical and radioactive properties of this element, Hahn deduced that uranium Z and uranium X_2 are isomeric nuclei. The problem of uranium Z has been taken up recently by Feather and Bretscher (*Proc. Roy. Soc.*, 165, 542; 1938). It should be noted that, for many years, uranium Z and uranium X_2 were the only known example of an isomeric pair.

After the discovery of artificial radioactivity, the study of isomerism received considerable impetus on account of the experimental material assembled in the course of research on artificial radio-elements. The first *certain* example of an isomeric pair to which it has been possible to attribute a mass number ($A = 80$) in the domain of the artificial radio-elements was furnished[3] by the study of the radioactivity produced in bromine by neutrons (slow and fast) and by γ-rays of great energy.

Then, as the experimental material on artificial radio-elements has increased, the number of pairs of nuclei which are undoubtedly isomeric has grown to such an extent that it is not possible to quote here all the investigations which have been published on the question. More than thirty such pairs are known and there is no doubt that the number still unknown is much greater. We can say, now, *that nuclear isomerism is by no means an exceptional phenomenon.*

It is natural to think that the physical difference between two isomeric nuclei is connected with two states of different excitation of the same nucleus (let us say ground state and first excited state). But in this case, how could the upper state be metastable, that is, how could it live for any length of time (greater than one day, in some cases)? By what mechanism would it be preserved from destruction in a very short time by the emission of an electromagnetic radiation? Weizsäcker has answered this question[4].

According to Weizsäcker's *hypothesis*, nuclear isomerism may be explained by assuming that *the lowest excited state of the nucleus has an angular momentum differing by several units from that of the ground state.* Selection rules may then be invoked to weaken considerably the probability per unit of time of the transition from the upper to the ground state of the nucleus. Of course, experiments which make it possible to test the truth of Weizsäcker's hypothesis are of great interest.

One of the most important points is the study of the γ-radiation eventually emitted in the transition from one isomeric state to another: I say "eventually emitted" because, the nucleus being radioactive, the upper state corresponding to one of the isomeric forms may be destroyed by an ordinary β transition. The γ-ray – β-ray branching ratio will depend on the relative life-times for the two modes of decay. The first researches made to observe this γ-radiation failed. But it should be noted[5] that the considerable difficulty in detecting this radiation might be due to the fact that transitions between isomeric nuclei can be strongly converted: in this case electrons of small energy would be emitted and not γ-rays.

The very complete theory of the internal conversion of radiations emitted in the transitions between isomeric states[6], given by Hebb and Uhlenbeck, Dancoff and Morrison, has shown that these radiations must have internal conversion coefficients of approximately 1. Since these calculations are based on Weizsäcker's hypothesis, it can be concluded that *experiments which prove that the conversion coefficient in question is very high would indicate, to a certain extent, that Weizsäcker's hypothesis is correct.*

Indeed, in the case of the isomerism of radio-rhodium, Pontecorvo[7] has observed a radiation of low-energy electrons, which he interpreted as an electron line emitted in the transition from the metastable state to the ground state of the nucleus.*

At the present time, after a number of recent experiments, *there is no longer any doubt as to the fact that these transitions are generally strongly converted.* In particular, in the cases of isomeric nuclei of radio-bromine[8] and of element 43[9], strong lines of conversion electrons have been photographed in the Wilson chamber or in the magnetic spectrograph. Of course, the internal conversion is accompanied by emission of X-rays: as a rule, the analysis of these rays is an invaluable test in the interpretation of these phenomena[8,10].

It is interesting to find possible genetic relations between isomeric states of the same nucleus (β-radioactive): in this direction an extremely brilliant method has been described by Segrè, Halford and Seaborg[11], who have succeeded in *separating*, one from the other, the two isomeric forms of radio-bromine. The principle of their method is as follows. Suppose the element, of which the isomeric states are being studied, can give compounds suitable for the application of the Szilard-Chalmers method of concentration. When the isomer in the upper state decays to the lower state, there is a γ-ray emission: corresponding recoil may be sufficient to knock the decayed atom out of the compound. The daughter activity can then be separated, as in the Szilard-Chalmers method.

---

* Note added in proof. A similar conclusion was independently obtained by Rusinow and Yusephovitch [*C. R. Acad. Sci. U.R.S.S.*, 20, 9 (1938)] who observed a soft electron radiation in the case of isomeric forms of radio-bromine.

This method, which has been successfully applied in several cases[12], can then be used (a) to separate known isomers in some cases; (b) to discover the existence of isomeric pairs, still unknown, in the study of artificial radioactivity.

Moreover, it has given a striking new proof that the transitions between isomeric states are strongly converted: in effect, the recoil due to the γ-emission is not sufficient to knock the decayed atom out of the compound, while the recoil of a conversion electron can be sufficient.

So far we have discussed radioactive isomers: the isomerism, in this case, implies a difference in the life-times of the isomers. It has been noticed by Pontecorvo[5] that β-stable nuclei with a metastable excited state ought not to be very rare and should be revealed by the study of the radiation emitted by this metastable state. These nuclei are interesting for the understanding of nuclear isomerism, because the radiation corresponding to the transition from one isomeric state to the other is not troubled by the presence of β- or γ-rays. It should be possible to obtain a β-stable nucleus in a metastable state, after a nuclear transmutation or a radioactive disintegration.

Dodé and Pontecorvo[13], by bombardment of cadmium with fast neutrons, have obtained an activity ($T = 50$ min.) which chemical proofs have shown to be due to an isotope of cadmium. On the other hand, there is no question of a reaction of simple neutron capture or of an $n,2n$ reaction. They interpreted the soft radiation emitted by cadmium (50 min.) as proceeding from a metastable state of an isotope of cadmium; the reaction of excitation without capture by fast neutrons (reaction n,n), having a considerable cross-section (some 10^{-24} cm.[8]), it is not impossible, indeed, that part of the nuclei so excited might fall into a metastable state.

Segré and Seaborg[9] have observed a metastable state of element 43, decaying (only a line spectrum of electrons) with a 6-hour period into the ground state, which is stable or perhaps radioactive with a long life: the 6-hour activity is daughter of a β-radioactive molybdenum.

A very interesting case has been observed and studied thoroughly by Goldhaber, Szilard and Hill[14]. They have obtained by the n,n reaction already quoted, a metastable state (^{115}In*) of ^{115}In, decaying with a period of 4·1 hours; moreover, the same state can be obtained after the disintegration of a radio-cadmium ($T = 2·5$ days). The radiation emitted by ^{115}In* has not yet been sufficiently studied; its properties are of the greatest interest both for the understanding of the nuclear isomerism and for that of isobaric pairs. In effect, ^{115}In and ^{115}Sn are one of the rare cases of stable neighbouring isobaric nuclei: ^{115}In* might then decay into ^{115}Sn (β-emission) or into ^{115}In, or into both together.

The same metastable state of ^{115}In has been obtained also by irradiating indium with 5·8 Mev. protons (reaction p,p), by Barnes and Aradine[15]. Nevertheless, it is not yet clear whether the mechanism of nuclear excitation is that discussed by Weisskopf, that is, excitation by the action of the electric field of the proton[16].

In all these cases and in others studied more recently[17], the metastable states of stable isotopes are obtained from *nuclear transmutations*.

Lazard and Pontecorvo[18] have tried a new method, by which *it would be impossible to transmute the nucleus* and, consequently, to obtain artificial radio-elements, the presence of which may interfere with the investigation.

This method consists of irradiating the target with a continuous spectrum of X-rays, the energy of which is less than the dissociation energy of the nuclei. Suppose the radiated nuclei have a metastable state; the X-rays may excite higher levels of the nuclei; a part of the nuclei thus excited can fall into the metastable state, and it is the radiation from this state which can be observed. The maximum energy of the continuous spectrum utilized was 1,850 kilo-volts: indium gives an activity of approximately 4 hours period, which is obviously due to the same metastable state ^{115}In*, of which we have already spoken. Similar results on the stable nuclear fluorescence of indium were obtained by Collins and others[19].

There is no doubt that new isomers of β-stable nuclei will be discovered, in the course of research undertaken in different laboratories; systematic research on the radiations emitted by metastable states will certainly be very useful for the understanding of nuclear isomerism.

In conclusion, we may remark that it is very probable, on account of the great number of known isomers, that the radiative transitions of life-times between, say, 10^{-7} sec. and 1 sec. are much more frequent than is generally supposed. These transitions, on the other hand, are strongly converted[6]. We would expect[20], consequently, that *transitions of this kind, with conversion coefficients approximately* 1, *may be found frequently*.

Indeed, in the radiation emitted in the capture of slow neutrons by gadolinium, a strong component of soft electrons has been observed by Amaldi and Rasetti[21] (life-time less than 10^{-3} sec.). Soft electronic components have also been observed in the capture of slow neutrons by other nuclei[12]. On the other hand, these strongly converted transitions may play a considerable part in the interpretation of γ- and X-spectra emitted by certain natural radio-elements[22].

RECENT ADVANCES IN RADIO ENGINEERING

RADIO MEETING IN WASHINGTON

A JOINT meeting of the Institute of Radio Engineers and the International Scientific Radio Union (American Section) was held at Washington, D.C., during April 28–29, 1939. Twenty-four papers on the more fundamental aspects of radio communication were presented.

A paper of particular interest, by D. R. Goddard, RCA Communications, Inc., reported reception at Riverhead (Long Island), N.Y., of British television transmissions on 41·5 and 45·0 megacycles from Alexandra Palace, London. The British afternoon programmes, between 9.30 a.m. and 11.30 a.m. New York time, could be received at times during certain winter months with some clarity. The author showed motion picture reproductions of images received on a number of occasions, both clear and distorted. Multiple path transmission was believed to be responsible for some of the distortion. In the past few years, the latest date for which reception is possible has been steadily receding from March through February to January, and it seems probable that next winter no reception at Riverhead of these signals will be possible after December 31.

Prof. Leon Brillouin of the Collège de France presented a comprehensive theoretical discussion of the transmission of electromagnetic waves in hollow conductor pipes, and reported confirmatory experimental work. Pipes of elliptical cross-section have been investigated, as well as those of square cross-section. Acoustic analogies, as discussed by M. Brillouin (*J. Phys.*, 1906), have been found of material assistance in these studies. An application of this investigation is to the design of tuning units of small attentuation for very high frequencies.

W. E. Jackson, of the U.S. Civil Aeronautics Authority, described the use of ultra-high frequencies, as 63 megacycles, in radio aids to air navigation. These frequencies reduce multiple-course indications, and are particularly suitable for aircraft application where usual horizon limitations do not apply.

H. T. Stetson, of the Massachusetts Institute of Technology, reported corroboration of a lunar effect of radio transmission which he discovered and published several years ago. A large number of observations have been examined, and appear to yield fairly consistent results among themselves, indicating increased field strengths as the moon nears the meridian. Reference was made to a discussion of lunar effects by Appleton (NATURE, July 9, 1938, p. 71).

B. Trevor, of RCA Communications, Inc., reported measurements of attenuation at 500 megacycles and 250 megacycles through 500 feet of woods and underbrush, also over low scrub pines.

J. T. Henderson, J. W. Bell and H. R. Smyth, of the National Research Council of Canada, described a 12-inch cathode-ray direction finder and its application to determine the direction of atmospherics. A cathode-ray direction finder equipment, received some time ago from the Radio Research Board of Great Britain, was used at Ottawa. At Forrest, Manitoba, a newer direction finder, designed and constructed by the authors, was used, and avoided defects found in the older instrument. Observers in Florida and Puerto Rico co-operated, particularly in studies of hurricane disturbances. While it is not yet possible to locate storms by these directional observations of atmospherics, before the Weather Bureau locates them by aeroplane observations, such early location of storms is an object of the work.

S. S. Kirby and F. R. Gracely, of the U.S. National Bureau of Standards, reported comparisons of signals at broadcast frequencies received at Washington from Buenos Aires with signals received from Rennes, France, and other European stations. The measurements have usually been made from 1 to 3 a.m. Washington time. The South American path averages about twenty times as good as the European path, both as to average field intensity and as to range of night-to-night variations of field intensity. The observed transmitting conditions were compared with co-existing magnetic disturbances, and it appears that the poor transmitting conditions on the northern path (auroral zone) may persist several days after the magnetic disturbance has ceased, the day following cessation of the magnetic disturbance often being particularly bad.

Ralph Stair and W. W. Coblentz, of the U.S. National Bureau of Standards, described a precision instrument sent aloft with balloons for observing and reporting to the ground the distribution of ozone in the stratosphere. There is used a precision method of making such measurements by measuring the change in spectral distribution of ultra-violet solar radiation at different heights as the balloons rise. Measurements of intensity in the ultra-violet are made by a special cadmium photo-electric cell which covers the range from about 2800 A. to 3300 A., and these are transmitted to the ground by a small radio transmitter including a relaxation oscillator. The instrument has been described in the March 1939 *Bureau of Standards Journal of Research*. It has been sent up to heights of 27 km.; about two-thirds of the total ozone lies below this height. Maximum ozone content has been found at heights of about 25 km.

Andrew Alford, of Mackay Radio and Telegraph Co., reported studies at high frequencies of characteristics of antenna arrays. He described marked differences in the phase of signals received over relatively long distances from two similar transmitting antennæ, only a few hundred feet apart, operating at the same time on the same frequency. The keying of the two transmitters was interlocked, and the signals were received and compared at the receiving station as to phase and intensity on a cathode-ray oscillograph. It appears that the construction of a directive transmitting array to obtain gain may fail of its purpose if the signals from different antennæ arrive out of phase, due to transmission over different paths. Proper phasing of inputs at the transmitting array may be an effective control, to get proper co-operation between the different antennæ.

R. C. Colwell and A. W. Friend, of the University of West Virginia, reported studies of tropospheric flections at about 2,400 kc. Preliminary tests in njunction with data from simultaneous aeroplane ights indicate direct connexion with temperature d humidity variations in the troposphere, as flection at a temperature front. These reflections ay be susceptible of use for weather prediction, oth for primary data in localities where neither roplane flights nor *radio sonde* ascents are available, d also as secondary data to interpolate between ch regular flights and ascents at established ations (see NATURE, July 1, 1939, p. 31).

L. V. Berkner, of the Carnegie Institution of ashington, who has just returned from an extended isit to Australia, described foreign installations and chnique for ionospheric exploration. Observations t the Watheroo (Western Australia) station of the arnegie Institution were discussed in particular etail, especially with reference to the formation of he *E*-region, and there was pointed out the importnce of co-ordination of ionospheric measurements rom a number of stations widely separated over the arth, and the extensions of ionospheric knowledge lready so obtained.

N. Smith and A. S. Taylor, of the U.S. National ureau of Standards, described a project now under ay to predict monthly average ionospheric chareteristics and maximum usable frequencies for undisturbed days, for several months in advance. Such predictions are now being published each month in the *Proceedings of the Institute of Radio Engineers*. These predictions are related to sunspot numbers.

J. A. Pierce and H. R. Mimno, of Harvard University, reported on the reception of radio echoes from distant ionosphere irregularities. Studies of numerous reflection patterns strongly indicate that the delayed echoes are returned from regions where there is a marked curvature of the *F*-layer, as at the edge of the sunlit zone. There may be successive reflections between the *E* and *F* layers.

Other papers covered a comprehensive study of the characteristics of noise in radio reception, a field strength survey on 52·75 megacycles in the New York area, transmission on 7 megacycles between Los Angeles and San Francisco, a comparison of shunt and series excitation of a 0·55 wave-length uniform cross-section broadcast vertical radiator, inductive output tubes, shielding of radio-frequency ammeters, and additional ionosphere studies.

The meeting was preceded and followed by a number of informal round-table discussions of groups specialized in certain aspects of ionosphere and transmission phenomena. It is expected that a number of the papers presented will be published in the *Proceedings of the Institute of Radio Engineers*.

BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

A MEETING of the trustees of the Beit Memorial Fellowships for Medical Research, Sir Alfred Beit, the Earl of Onslow, Lord Harlech, Lord Rayleigh, Lord Macmillan of Aberfeldy, Prof. T. R. Elliott and Dr. H. L. Eason, was held on July 19, 1939. They received with regret the resignation from the advisory board of Sir F. Gowland Hopkins, who throughout the long period of twenty-five years has given wise counsel at the meetings of the Board and in his Biochemical Department at Cambridge has directed the research studies of perhaps a greater proportion of those elected to Beit Fellowships than any other head of a department has done. They also regretted the resignation of Sir Patrick Laidlaw after eight years of keenly attentive work. These vacancies were filled by the appointment to the Board of Prof. R. A. Peters, Whitley professor of biochemistry, University of Oxford, and of Mr. Paul Fildes, bacteriologist on the scientific staff of the Medical Research Council.

Former holders of fellowships have recently received appointments as follows: C. H. O'Donoghue (fellow 1912–13) to be professor of zoology at the University of Reading; J. T. Irving (fellow 1926–28), to be professor of physiology in the University of Cape Town, South Africa; G. F. Marrian (fellow 1927–30) to be professor of chemistry in relation to medicine in the University of Edinburgh; F. H. Smirk (fellow 1930–34), to be professor of medicine in the University of Otago, New Zealand; and H. P. Himsworth (fellow 1932–35), to be professor of medicine in the University of London and director of the Medical Unit at University College Hospital.

It was in 1910 that the first Beit fellow, now Sir Thomas Lewis, was elected, and last year's election in 1938 brought the total of all fellows elected to exactly 200. Women are eligible and have been elected from 1910 onwards, their total being 30 out of the 200. Of the 170 men, 6 have been elected to the fellowship of the Royal Society, and no fewer than 34 have already been appointed to university professorships, of which 5 were in physiology, 5 in pharmacology, 5 in medicine and 9 in chemistry or biochemistry. Eight of these past Beit fellows hold professorial chairs in the Dominions over-seas. None of the women has yet been promoted to a university professorship, though at least six of them are doing work of much distinction and one has for some years been director of an important research laboratory. The opportunities for a woman to obtain a university chair in a scientific subject are still restricted.

Though the Beit fellows have come from all parts of the British Empire and have afterwards gone to laboratory posts all over the world, in their choice of a place of research during their fellowships they have tended to group themselves at three main centres. Out of the total 200, the laboratories at Cambridge have held 55, and 29 of these were personally directed by Sir Gowland Hopkins in the great Biochemical School that he developed in the Dunn Laboratories immediately after their opening in 1925. University College and University College Hospital in London together have provided opportunities for the work of 39. The Lister Institute of Preventive Medicine has accepted 35. The trustees have expressed their gratitude to the directors of these and of the other laboratories in Great Britain and elsewhere who have not only guided the work of the Beit fellows attached to them, but also provided the laboratory cost of that work.

The original Trust in London was founded by Sir Otto Beit as a memorial to his brother, Alfred Beit, a colleague of Cecil Rhodes in his great plans for the future of British South Africa. The names of both these brothers, members of a German family from Hamburg who later received British naturalization, will live in their benefactions for the advantage of the Empire. Mr. Alfred Beit left large sums for South African universities, and also founded a trust for the development of communications in South and Central Africa. This trust has been of material assistance in the development of Rhodesia. Empire Day, 1939, saw the opening of a great bridge 500 yards long over the Zambezi, north-west of Salisbury and joining the two Rhodesias. The gift of this "Otto Beit Bridge" costing £180,000 came ten years after the building of the "Alfred Beit Bridge" at a cost of £130,000 over the Limpopo farther south; and much besides has been granted by this trust for other bridges, for education, school buildings, maternity homes, and other social services.

The Beit Trust for Medical Research, which is established in London, cannot afford such material evidence of its benefits, though actually a total of nearly £190,000 has been disbursed in fellowships since 1910. But the foregoing summary of the positions now held by past Beit fellows, men and women drawn from all parts of the Empire, shows how great and widely spread have been the intellectual gains through these fellowships. They have enabled men to live for three or four years whole-heartedly in an environment of research and by so doing to learn to devote the rest of their lives to scientific thought.

All correspondence of fellows and candidates should be addressed to Prof. T. R. Elliott, Honorary Secretary, Beit Memorial Fellowships, University College Hospital Medical School, University Street, London, W.C.1.

The following elections to new fellowships were made:

Fourth Year Fellowships (£500 a year): Dr. I. Berenblum, to continue his work on the production of cancer by skin irritants, and to study the metabolism of living cells in tissue culture (School of Pathology, University of Oxford); T. A. H. Munr to continue his studies of the role of inheritance i mental disorders (Royal Eastern Counties Institutio Colchester); Dr. A. Neuberger, to extend his wor on the chemistry of amino-sugars in elucidation the structure of natural compounds (Department Pathological Chemistry, University College Hospit Medical School, University of London); Dr. R. Pumphrey, to continue his studies on the nervou system of cephalopods and on the auditory process in insects (Zoological Laboratory, University Cambridge, and the laboratory of the Marine Bi logical Association, Plymouth).

Junior Fellowships (£400 a year): Dr. V. F Booth, for research on (1) the internal constituent of bacteria by means of a wet-crushing mill, (2) ca bonic anhydrase (Physiological Laboratory, Un versity of Cambridge); E. G. L. Bywaters, fo research on rheumatoid arthritis (British Post graduate Medical School, University of London) Dr. W. I. Card, for research on the inhibition o gastric motility and secretion by experimental studie on man (Medical Unit Laboratories and Sherringto School of Physiology, St. Thomas's Hospital Medica School, University of London); Dr. Hans Heller, fo research on the antidiuretic principle of post-pituitar extract (Medical Unit Laboratories, University Colleg Hospital Medical School, University of London); Dr M. S. Jones, for investigations on insulin treatment o schizophrenic mental states (Maudsley Hospital, Den mark Hill, University of London); Dr. B. Levi to investigate the effect of spatial configuration o antigens on immunological reactions (Clinical Chemical Laboratories, London Hospital, University o London); I. Mackenzie, for immunological investigations on constituents of tumours (Department o Surgical Research, University of Edinburgh); D A. F. Rawdon-Smith, for research on congenital dea ness (Physiological Laboratory, University of Cambridge); Dr. B. R. Record, to investigate the specifi soluble substance found in the tissues in acut vaccinial infection (Lister Institute of Preventiv Medicine, University of London).

TRENDS OF PROGRESS IN TECHNICAL CHEMISTRY

THE annual meeting of the Society of Chemical Industry, held at Exeter on July 10–15 under the presidency of Dr. V. G. Bartrow, the eminent Canadian industrial chemist, was noteworthy for a symposium on "The Trend of Progress" to which important papers on various subjects in the field of chemical technology were contributed (*J. Soc. Chem. Ind.*, 58, 587, 613, 635; 1939).

P. W. Tainsh (chief chemist to Lever Bros., and Unilever, Ltd.) reported on progress in oils, fats (other than edible) and detergents, pointing out that during the last twenty years important advances have been made in the methods of treating oils and fats to render them suitable for soap-making, and in particular bleaching and hydrogenation processes have been remarkably improved. The main development in connexion with the technical bleaching of oils has been in the application of activated bleaching earths. At one time the bleaching of oils was mainly carried out with natural earth, such as fuller's earth and with this the bleaching effect obtained with a oil such as palm oil, for example, was strictly limited Activated earths are obtained by treating the natura earths with hydrochloric or sulphuric acid and washing the earth down to a limited free-acid content Tallow is still bleached for soap-making purposes b treatment with activated carbon after neutralization

The progress made in technical hydrogenatio during the last ten or fifteen years has been of grea benefit to the soap-maker, and the hardened produc may be so controlled that suitable artificial fats ma be obtained from such materials as whale oil an fish oils which are equal in all respects, and for som purposes superior, to tallow. The use of preservative in preventing oxidation has been developed. Improvements in soap-making, drying and milling soap, th production of soap powders and soap products, ar recorded. One of the latest developments is that o e so-called soapless detergents. Normal soaps are dium and potassium salts of long-chain carboxylic ids. In soapless detergents the long hydrocarbon ain is retained, but by the introduction of a variety solubilizing groups other than the simple carboxyl oup, products are obtained which are not affected hard water. Such products are sulphated higher cohols (C_{12} to C_{18}), condensation products of fatty ids with isethionic acid, products of interaction of tty acid chlorides and methyl taurine, and of the lphonation of the product from high molecular eight phenols and ethylene oxide. Many of these roducts are in industrial use, although for general rposes it would appear that the newer detergents e still inferior to soap.

The trend of progress in cosmetics was reported by . S. Redgrove. Titanium oxide may replace zinc xide as a white face-powder. Lake colours and nthetic iron oxides are used for tinting, cellulose itrate nail enamel has replaced wax and powder olishes. Other topics dealt with included hair dyes ad creams, shampoos (including soapless products) nd face creams.

The cellulose industry, with special reference to he paper and allied industries, was dealt with by . Grant (chief chemist to J. Dickinson and Co.). ellulose derived from wood takes the first place mong the raw materials, although esparto grass is idely used in Great Britain for printing papers. riginally, three main processes were used for producing wood pulp: the acid process (sulphite pulp), e alkaline process (kraft pulps), and the mechanical rocess (for newsprint). The paper manufacturer is ow met in competition in the pulp market by the akers of rayon (artificial silk), plastics and explosives. Other types of wood are now being investigated, and in Germany the exploitation of beech ood has been fostered by a nationalistic policy and now reaching considerable proportions, and esparto om Italian North Africa is now being exploited in aly, where sunflower stalks, hemp stalks and straw re also making the country largely independent of utside supplies. A combination of the two previously parated processes of isolation and bleaching is now ccupying the cellulose industry, one process being hlorination with elementary chlorine. This enables bres to be used which were previously unsuitable r paper pulp. A process still undeveloped commercially is the extraction of impurities from mildly rocessed raw material by means of organic solvents.

The cellulose textile industry was discussed by L. A. Thomas (of Messrs. Courtaulds, Droylsden) nder the headings of production, dyeing, finishing nd testing. Various modifications in the properties f the viscose fibre are possible in new processes, ome varieties, for example, being suitable for motor yre cords, which have to withstand temperatures the region of 100°, and also the fibres imitating ool. Modifications in the acetylation of cellulose r the production of acetate rayon include the use f special solvents which are miscible with the sterifying agents, but prevent dissolution of the ellulose ester. In the dyeing section, an important end is the production of coloured yarn by the incororation of insoluble pigments in a finely dispersed orm in the rayon spinning mass, a process known as pin-dyeing. This is overcoming the difficulty of roducing fast shades on acetate rayon. Suitable igments are carbon black and organic fast pigments. n the finishing section, the use of crease-resisting finishes by suitable impregnation of the fabric with solutions which on heat treatment produce a resin or polymer *in situ*, is extending. The technique of stiffening fabrics by employing cellulose esters or ethers, either as an interlayer or as woven threads, which are then plasticized and hardened, is used for semi-stiff shirt collars and cuffs. Viscose staple fibre is finding an increased use in the cotton trade.

In a paper on insecticides by J. T. Martin and F. Tattersfield (of Rothamsted Experimental Station) it is pointed out that the use of these materials has very greatly increased in recent years. The older products are still of great importance, although the supremacy of some has been challenged. Among stomach poison insecticides, lead arsenate has so far withstood all attempts to replace it. Of the many hundreds of synthetic compounds tested, phenothiazine (thiodiphenylamine) has aroused the greatest interest; among other things it is a potent poison for the mosquito larva. Nicotine bentonite is effective against codling-moth. The use of glycero-borates as a dressing in the treatment of blow-fly on sheep has given very satisfactory results. The application of various fluorine derivatives, including sodium silicofluoride, as moth proofing of fabrics gives satisfactory results. Among contact insecticides, nicotine, rotenone-containing plants, pyrethrum, quassia and petroleum are predominant, and recent progress is mostly concerned with their chemistry, mode of application and range of utility. The development of winter washes as ovicides has been a marked feature of the last twenty years. Experiments indicate that some insect pests can become highly resistant to the toxic substances used in their extermination.

Fungicides are reported upon by H. Martin (Research Station, Long Ashton, Bristol). Attention has been given to the factors affecting the efficiency of fungicidal treatments, such as the amount of fungicide retained on the treated plant or seed. This is connected with the wetting properties of the spray. Instead of water, a carrier of the active spray ingredient may be a liquid of low surface tension exhibiting low contact angles, such as kerosene and aqueous solutions of surface-active materials. Another promising method is to dissolve the active constituent in an oil and then emulsify this in an aqueous phase; an example is a nicotine - cottonseed oil - Bordeaux spray. The number of established active constituents of fungicides is limited to sulphur, copper, mercury, formaldehyde, and a few less widely used materials, and recent experimental work has modified generally accepted views of the action of these.

The paper of Sir John Russell (director of the Rothamsted Experimental Station) on crop production dealt with new crops, such as sugar beet, mechanization, increasing grass land, and the fertility of British soils. Sir John finds no evidence for the deterioration of British soils. The effects of small quantities of boron, manganese, copper and zinc in plant nutrition is now recognized, and other elements such as cobalt, molybdenum, selenium, fluorine and iodine in appropriate quantities considerably influence the nutritive value of the crop and animals. The question of the effect of reduced production of farmyard manure on soil fertility is answered by the statement that there is no evidence that it has lowered the fertility of British soils; there has been a corresponding shrinkage in area of arable land, and the grassland which has replaced it does not need farmyard manure.

GEOTHERMIC POWER IN ITALY

THE formation of a large company in Italy—Larderello S.A. per lo Sfruttamento delle Forze Endogene—with a capital of 54, and perhaps later of 150, million lire, for utilizing the natural heat sources of Italy, may well be regarded as a consummation of the life work of Prince Ginori Conti. He is honorary president of the new company which has taken over many of his patents together with his company, the Societa Boracifera di Larderello; and among other distinguished people on the board of directors is Dr. G. Fauser, the inventor of the well-known electrolytic cell.

In a small book published last year, Prince Conti described his new and well-equipped laboratory for research in this field, which he says dates back to 1906, and is a continuation of "the long and noble tradition" originating with Hofer who, in 1777, discovered boric acid in the Lagon Cherchiaio di Monterotondo. In 1916 was established the first and still probably the only Centrale Geotermica in the world, developed later into a Supercentrale of some 90,000 kw. The yield of gas and fume from the fumaroles (Ital. fumaioli or fumaruoli) and soffioni has increased very remarkably from a few hundred thousand kilos to two million kilos of fume or vapour per hour, besides enormous quantities of gas. The latter occurs in the proportion of about 30 litres gas to 1 kilo of fume, and consists of 93 per cent carbon dioxide, 2·5 per cent hydrogen sulphide, and combustible residue the composition of which is approximately 38 per cent hydrogen, 39 per cent methan 22·6 per cent nitrogen, together with small propo tions of helium, neon, argon, krypton, and xenon.

A well-equipped research station has for some tin been engaged on the analysis and industrial pos bilities of these various products.

The work is under the personal supervision Prince Conti, with the assistance of his son, D Giovanni Ginori Conti, Prof. Umberto Sborgi ar other distinguished Italian men of science ar engineers. The organization comprises librar administrative offices, and various departments f chemical, physical, geological, mineralogical, geoph sical, and seismographical investigations, not only connexion with the fumaroles and soffioni but also the 'boric acid fields' around Larderello. Since th operations of the new company extend to the who of Italy other similar research stations will doubtle be established in other districts, with Larderello headquarters. Provision is made, *inter alia*, for hig and low-temperature and high-pressure investigation the former ranging from −254° to 2000° C. and th latter up to 1000 atmos. Semi-large scale workin is also included, and a pilot plant has been installe for dealing with 150 cu. m. per hour. Among th principal items in the research programme at presen are the recovery of helium and other rare gases, al of hydrogen, methane, and a synthesis gas mixtu of hydrogen and nitrogen, presumably for ammon production and derivatives, such as nitric acid, etc.

TRAINING OF ENGINEERS

IN the June issue of the *Journal of the Institution of Civil Engineers* is published the record of a joint informal meeting of the three Institutions—Civil, Mechanical and Electrical—at which Mr. T. G. Rose introduced the subject "The Importance of a Training in Management for Engineers". Following the two claims (1) that the fundamental principles governing sound industrial management were now sufficiently clearly defined to be teachable, and (2) that a knowledge of these principles would be of advantage to an engineer in the pursuit of his profession, he indicated several systems on which the desired instruction might be given.

That the need of this is keenly realized was made evident by the brisk discussion, but the views expressed were very divergent as to how and when the training should be given. Some considered that it could only be usefully imparted to those who had had experience, while others held that the principles could be taught at an early stage. One suggestion was that the three Institutions should arrange lectures and meetings at which the problems of industrial management would be discussed by practical men. This would, no doubt, provide a finishing course which could be read and studied by all those, wherever situated, who had already been taught the fundamental principles. No clear indication was given as to the method of providing this elementary instruction, but there was a suggestion that it might form part of the production side of th National Certificate scheme. This, however, already heavily burdened and a little consideratio will show that, unless the subject is made optiona it will to some proportion of the students be a di tinctly unwelcome one forced upon them.

In the same issue of the *Journal* it is interestin to note the intimation that the Council will promot a conference on engineering education and trainin during the course of next session and has invited th universities and other bodies to appoint represent tives to form a general organizing committee. Th time is ripe for such a conference, for it is near thirty years since the last, and one would expect tha to ensure steady development, five-yearly co ferences would be held. At present it is very large left to the colleges themselves to devise systems an curricula, and the several branches of the professio take but a perfunctory interest in a matter so close affecting them. In consequence, there is a very lar class of students whose interests are wholly neglecte by the Institutions. This class consists of all tho who are outside the reach of the recognized college and for whom some authoritarian training should envisaged as at present is provided for those mo fortunately placed. Some responsibility rests o those who control the National Certificate arrang ments in respect of the thousands of students wh are, in effect, barred from them.

SCIENCE NEWS A CENTURY AGO

Baron de Prony, 1755-1839

On July 29, 1839, the distinguished French mathematician and engineer, Gaspard-Claire-François-Marie-Riche, Baron de Prony, died at Asnières, near Paris, at eighty-four years of age. For many years he had been the senior member of the Corps des Ponts et Chaussées and was famous both as a writer and a constructor. Born near Lyons on July 11, 1755, he had been trained under Perronet, "the Telford of France", at the École des Ponts et Chaussées, and afterwards became his assistant. With Perronet, too, he visited England. During the Revolutionary era, Prony formed one of the commission entrusted with the reformation of the French weights and measures and with the great survey of France. In connexion with this he organized and trained a body of computers for forming the logarithmic tables required, the result being seventeen large volumes of tables, afterwards deposited in the Paris Observatory. In 1798 he was raised to the rank of inspector-general in his corps and soon afterwards succeeded Chezy as director of his old school.

Though he declined to join the group of scientific men who accompanied Napoleon on his expedition to Egypt, Prony was employed by Napoleon on many considerable works in Italy, and with Count Fossombroni was entrusted with the drainage and improvement of the Pontine Marshes. His principal literary work was his "Nouvelle architecture hydraulique" published in 1790–96. He was one of the first professors of the famous École Polytechnique and one of the first members of the Institut de France. In 1817 he was made a member of the Bureau des Longitudes, in 1818 the Royal Society elected him a foreign member, in 1827 he was made a baron and seven years later a peer of France.

Dumont d'Urville's Voyage in the *Astrolabe*

On July 30, 1839, Captain Dumont d'Urville wrote from the *Astrolabe*, then at the island of Mindanao: "Our navigation since the 2nd of July, the day of our departure from Singapore, has been fertile in results. We have touched at Sambas, in the island of Borneo, closely reconnoitred the islands of Natunas, Balambangan, Banguey, and the northern portion of Borneo. Finally we have passed four days in the road of Sooloo. The people of these several places have acquired from our communications clearer notions in relation to the flag and power of France: they desire much to see the rest of our ships. I am about to spend a week at Samboangan. I shall depart there on the 6th of August, and reckon on reaching Port Jackson about the middle of December."

Society for the Diffusion of Useful Knowledge

On August 2, 1839, this Society sent out a letter from its headquarters, 59 Lincoln's Inn Fields, London, signed by Lord Brougham, which said: "It is the wish of the Committee of the Society for Diffusion of Useful Knowledge, to establish a correspondence among the various Mechanics' Institutions in England, and between them and this Society, so that neighbouring institutions, by dividing the travelling expenses of lecturers among them, may diminish the cost of each course of lectures; that one set of apparatus, or collection of models or specimens of natural history, or even one set of books, may serve for many institutions; and that local collections and duplicates from libraries and museums, may be interchanged all over the country".

By the issue of an annual report, correspondence and the interchange of suggestions, it was hoped to make the experience of one institution serve as a guide to others, and by collecting information to be able to issue an annual summary on the progress of adult education in Great Britain.

To further these objects, the Society called a meeting of representatives of institutions in London and neighbourhood which was attended by about forty, when a committee of delegates was appointed.

The Society for the Diffusion of Useful Knowledge existed from 1827 until 1846. It published a series of cheap books on science, history and literature, and also the *Penny Cyclopædia*.

UNIVERSITY EVENTS

Edinburgh.—At the graduation ceremonial on July 19 the honorary degree of doctor of laws was conferred on Dr. F. H. A. Marshall, fellow and dean of Christ's College, Cambridge, and reader in agricultural physiology in the University of Cambridge. On the previous day, Dr. Marshall declared open in the Edinburgh University Settlement the Wilkie Memorial Library, which has been established in recognition of the great interest which the late Sir David Wilkie and Lady Wilkie took in the work of Settlement.

Leeds.—Dr. E. C. Stoner, reader in physics, has been elected to the recently instituted chair in theoretical physics.

The following appointments have also been made: Dr. N. H. Chamberlain to be lecturer in textile chemistry; Arthur Johnson to be assistant lecturer in weaving mechanism; Dr. C. S. Whewell to be assistant lecturer in finishing and research assistant in the Textile Department; J. W. Roderick and W. A. Linning to be lecturers in engineering; J. F. Gaunt to be research assistant in dyeing; Dr. J. Stubbs to be temporary research assistant (for bracken investigation) in the Agricultural Department.

Prof. F. A. E. Crew, director of the Institute of Animal Genetics, Edinburgh, has been invited to deliver the Clive Behrens Lectures in the Agricultural Department during the two years 1939–1941.

London.—W. G. Barnard has been appointed, as from October 1, 1939, to the University chair of pathology tenable at St. Thomas's Hospital Medical School. Since 1931 he has been consultant histologist to the London County Council and pathologist-in-charge of the London County Council Central Histological Laboratory, Archway Hospital.

The title of reader in medicine in the University has been conferred on Dr. E. F. Scowen in respect of the post held by him at St. Bartholomew's Hospital Medical College.

The degree of D.Sc. have been conferred on the following: Miss Daphne Atkins (Bedford College), Miss M. C. Brough (University College), Dr. W. H. Linnell, University reader at the College of the Pharmaceutical Society, and J. A. B. Smith (Imperial College of Science and Technology).

R. M. Calder has been re-appointed to the Graham scholarship in pathology for a further period of one year from November 1, 1939.

APPOINTMENTS VACANT

Applications are invited for the following appointments, on or before the dates mentioned:

Principal Technical Officer and a Senior Technical Officer at Air Ministry Headquarters—Under-Secretary of State, Air Ministry (S2A/B3019), Berkeley Square House, W.1 (August 4).

Chief Assistant Engineer—Clerk of the County Council, County Buildings, Stafford (August 5).

Assistants Grade III—Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants. (quoting A340.0) (August 11).

Technical Officer—Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (quoting A399.0) (August 12).

Assistant Lecturer in Botany (Grade III)—Registrar, University, Liverpool (August 15).

Lecturer in Anatomy—Secretary to the University, Aberdeen (August 18).

Physical Chemist—Director of Research, Research Association of British Flour-Millers, Old London Road, St. Albans (August 19).

Lecturer in Biology—Secretary, Royal (Dick) Veterinary College, Summerhall, Edinburgh 9 (August 20).

Waterworks Engineer—Town Clerk, Town Hall, Bradford (August 28).

Lecturer in Electrical Engineering—Secretary, University, Edmund Street, Birmingham 3 (August 30).

Demonstrator in Physiology—Registrar, University, Liverpool (September 1).

Lecturer and Studio-Instructor (Ungraded) in Architecture—Registrar, University, Liverpool (September 18).

Head of the Physiology Department—Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (September 30).

DEMOCRACY AND LEADERSHIP

IN a volume entitled "Recovery: the Second Effort", Sir Arthur Salter outlined a scientific programme of recovery conspicuous for its vision and sense of values. He has now produced an equally comprehensive review* of the international ituation to-day, which outlines an equally scienific programme for retrieving security, no longer in the field of economics but in that of power politics. Beyond this, however, Sir Arthur has given us not only a frank and realistic picture of he grave dangers which confront democracy and all that it stands for to-day, not merely a challenge, but also a vision of hope. Through all the dangers which now confront democracy, he sees its innate strength. Its weakness can still be repaired in time f we but bring to the service of its virtues bred and nursed to the pursuit of peace, the sterner virtues of fortitude, energy, the will to act together, the free acceptance of discipline and sacrifice. Faults of organization and leadership can be made good if recognized, and the book is to be welcomed even if only for this reminder that with courage and vision, the recognition of danger and not the refusal to see it, we can yet eliminate the sources of weaknesses in the free democracies.

Sir Arthur opens with a trenchant analysis of the chief material and political factors involved n the present position, and sets in clear relief the dangers confronting the democracies and the factors likely to precipitate conflict or avert it. Scientific workers, no less than the general reader, should welcome this sane and concise review of the situation.

The second part of the book consists of a brief review of the events and ideas which have been responsible for the failure to achieve collective security in the last two decades through the League of Nations. In this review, emphasis is laid in the transformation of the character of the League from the start, through the abstention of the United States and later defections with their consequences.

Sir Arthur Salter urges the undesirability as well as uselessness of attempting amendment of the League Covenant at present. The main task in respect of the League is to keep its organization active and efficient by developing the useful work which it can continue on social, economic and financial and labour questions. This pertinent reminder of the valuable work which is still being done in a number of technical and scientific fields should not be lost on scientific workers. We must have regard both to the practical and to the ideal. The ultimate goal must be either the restoration of the League, or the construction of some other form of collective system, including the revision of treaties by collective negotiation. Until we achieve this, peace must be at best precarious.

The third part of the book, entitled "National Strength", which is the longest of the five, deals with the various factors in the domestic situation. It contains most of the detailed criticism which Sir Arthur allows himself and reveals to the full the author's rich administrative experience and capacity. It is this section, with its highly stimulating and suggestive remarks regarding leadership, that scientific workers should find of special interest. In the fourth part, Sir Arthur outlines his views on present policy to lay the foundation of a new peace. He sets forth proposals for the basis of the discussion of a general settlement with Germany when conditions make the reasonable discussion of such a settlement practicable as an example of what might be possible with the other Axis powers also, while in the fifth part of the book he discusses the strength and weaknesses of the democracies and totalitarian systems, and summarizes the policy and action required in defence of democracies.

---

* Security: Can we Retrieve It? By Sir Arthur Salter. Pp. xv+390. (London: Macmillan and Co., Ltd., 1939.) 8s. 6d. net.

The policy outlined by Sir Arthur has every claim to be described as a scientific policy and as such merits the attention and support of all scientific workers. He reiterates, for example, the case for a Ministry of Supply as a first step in the reorganization needed to enable industry to meet the vast demands of the war services, and the arguments in support of the case with which he has long been associated are marshalled with force and lucidity. Here again he is on ground that is already common with many scientific workers, and this chapter on industrial mobilization deserves their close attention.

Beyond such particular questions, this part of the book raises the fundamental questions of leadership in a democracy. By what is implied, as much as by what is said, Sir Arthur Salter indicates the limitations and defects of leadership in Great Britain in the last decade or more, the lack of vision, the failure not merely to foresee dangers but even to recognize their existence. Once again he directs attention to the dangers of professional departmentalism and to the obstacles it opposes to vigorous and effective action in any new field. Not only in regard to the storage of food and air raid precautions, but also in such matters as the location of industry, Sir Arthur Salter is seriously disturbed at evidence of failure on the part of the Government to realize what is involved, and the charge of executive incompetence which he presses home is the more impressive through its sober restraint

Inevitably such criticism raises the whole question of the selection of executive ministers in a democracy in times of such stress. Far closer co-operation between the Government service and the public is required if the economic adaptation necessitated in modern warfare is to be achieved and quick and vigorous action facilitated both by the Government and by industry.

To this end several specific proposals are made. The personnel of the Civil Service should at once be reinforced; at the top with the leading men in science and industry, and throughout its ranks with young men of energy and constructive ability, some of whom would be specialists and others, while without specialized experience, should have a trained and adaptable intelligence. In addition to full transfer, Sir Arthur suggests that competent men of energy and constructive abilit and useful specialized knowledge in finance an other business houses could be associated at onc with appropriate departments on a part-tim basis. Stress is also laid on the opportunity f private initiative and, in particular, it is suggeste that scientific men, without waiting to be consulte on particular questions, should take the initiati themselves by reviewing in turn the obviou problems in which scientific knowledge is not yet fully utilized.

In regard to the executive, Sir Arthur suggests small inner Cabinet of Ministers, relieved of depar mental duties, of suitable personal qualities t conceive and elaborate a general policy an furnished with an adequate and appropria organization. Stressing the importance of nation unity, he would broaden the basis of the Nation Government and suggests the appointment b Parliament of a Committee of Foreign Policy an Defence, consisting of twenty or thirty of the mo trusted members of all important parties or group

This criticism, which rarely fails to be constructive, is essentially a most stimulating an suggestive essay on leadership in democracy i which, for all its failings, Sir Arthur is a convince believer. Inadequate preparations are not due t inherent defects in our parliamentary system Some of the conditions which militate against th selection of requisite administrators and executive of ability are clearly indicated by Sir Arthur, bu his essay should at least stimulate much fundamental and constructive thinking about the selection and training of leaders for the highest position both in industry and in the State. Scientifi workers, no less than other members of the community, may well be grateful that Sir Arthur ha lent the weight of his unrivalled experience as a administrator to the exposition of the dangers an possibilities of the present situation. The realization of the menace, no less than the message o hope which breathes through the pages of thi book, may well assist in overcoming the obstacle to the more centralized direction and coheren planning of all our effort and stimulate the acceptance of the essential discipline and sacrifice. No should this constructive and inspiring book fai also to stimulate fundamental thought on th evolution of modifications in our democrati institutions, which will enable them to meet th strain more effectively and to throw up the leader required, while preserving unimpaired the grea traditions which are theirs and theirs alone.

REGIOMONTANUS AND KEPLER

(1) Leben und Wirken des Johannes Müller von Königsberg genannt Regiomontanus
Von Ernst Zinner. (Schriftenreihe zur bayerischen Landesgeschichte, herausgegeben von der Kommission für bayerische Landesgeschichte bei der Bayerischen Akademie der Wissenschaften, Band 31.) Pp. xiii+294+46 plates. (München: C. H. Beck'sche Verlagsbuchhandlung, 1938.)

(2) Johannes Kepler Gesammelte Werke
Herausgegeben im Auftrag der Deutschen Forschungsgemeinschaft und der Bayerischen Akademie der Wissenschaften. Band 1: Mysterium Cosmographicum. De Stella Nova. Herausgegeben von Max Caspar. Pp. xv+493. (München: C. H. Beck'sche Verlagsbuchhandlung, 1938.) 12 gold marks.

FOR those who date the beginning of modern astronomy from Tycho Brahe, and confine their interest to the subsequent period, there is good excuse. Yet there were great men before that time, who gave themselves to the task of dissipating the intellectual mists of the Middle Ages. As Copernicus is accepted as an impressive figure of the earlier sixteenth century, so Regiomontanus is an outstanding figure in the fifteenth. For various reasons it seems particularly difficult to arrive at a just estimate of the importance of Regiomontanus, and therefore a scholarly monograph on his life and work has great value and interest.

(1) Johann Müller was born in the year 1436 at Königsberg in Franconia, or in the neighbourhood. His surname conveys the family occupation, which was actually followed by his father, but it is by the name Regiomontanus derived from his birthplace that he has become universally known. Before he reached the age of twelve, it is said, he entered the University of Leipzig. That this was no ordinary instance of precocity was quickly shown. In 1448 Gutenberg produced the first printed calendar, giving places of the planets. For the same year there still exists a latin MS in the childish hand of Regiomontanus, which gives the positions of the planets at closer intervals and, as comparison with modern tables has shown, more accurately. Whatever other suggestion may be found to explain away this evidence that the ephemeris is the unaided work of a boy of twelve, it is shown here that no member of the University staff was capable of using the cumbrous astronomical tables available at that time. Leipzig was no place for a young astronomical genius, and so in 1450, still before he was fourteen years of age, Regiomontanus migrated to Vienna.

The choice of this University (founded in 1365) was a good one. It had a tradition in mathematical studies, and J. von Gmunden had established what was for that time a respectable school of astronomy. He himself had died in 1442, but other teachers were not wanting. At an early date Regiomontanus attached himself to Georg Peuerbach, his senior by thirteen years, who became qualified to lecture in the University only some time later. Another factor coinciding with the arrival of the young student and of no little importance for him was the introduction of humanism under the influence of Aeneas Silvius Piccolomini (afterwards Pope Pius II). Thus as a student Regiomontanus enjoyed excellent opportunities both in mathematical and classical subjects. The granting of his master's degree was delayed until his majority, and thereafter he lectured in the University, it might be on Euclid or it might be on Vergil. Throughout he enjoyed the position of favourite pupil and assistant to Peuerbach.

Little or no light is thrown here on the nature of his financial resources. The omission is easily understood, but it is to be regretted. Presumably he was self-supporting from necessity, and his sources of income were his horoscopes, such as those compiled for Leonora of Portugal on her marriage and for the future Emperor Maximilian I, her son, and a series of year-books. The second of these horoscopes is here reproduced among a number of interesting plates. The year-books contain astrological data then in great demand, not least among physicians for the practice of their calling. It would appear that the astrological rules were fixed and recognized. All that remained to be done was to supply the astronomical predictions according to the scientific skill of the computer. In his department Regiomontanus enjoyed a not undeserved reputation from early youth.

It is but fair to recognize that the crass superstition of the age provided a valuable incentive to true astronomical research. It became plain that the planetary tables, either the Alfonsine Tables, now two centuries old, or derivatives from them, like Bianchini's, were extremely defective. To Peuerbach and his pupil the errors presented a scientific problem. As the tables were based on Ptolemy, the line of advance in the first instance was to go back to the Almagest in order to understand clearly what his theory was. The outcome was the Epitome, a work which Peuerbach did not live to finish.

Now comes on the scene the Greek cardinal Bessarion, who arrived in Vienna as papal legate in 1460. In the following year he persuaded Peuerbach to return to Rome with him, accepting the condition that the pupil should go too. On the eve of setting out, Peuerbach died, and Regiomontanus went with the cardinal alone. With his cultured patron he spent the next four, or possibly six, years, living in Rome or visiting other cities like Venice, where he discovered a unique manuscript of Diophantus. The collecting or copying of manuscripts was part of his task. But his first great work in Italy was the completion of the Epitome Almagesti begun by Peuerbach. This is a version of Ptolemy simplified by the mathematical form introduced by the Arabians and incorporating some of their main results in astronomy. Its great importance lies in the fact that this version came later into the hands of Copernicus and Kepler, and its critical comments had undoubted influence. The second great work, also written in Rome, is that on trigonometry, spherical and plane. This belongs to the history of mathematics. It may be difficult to distinguish the parts that are truly original, but on questions of plagiarism the only safe course seems to be to assume that Regiomontanus knew all that was to be known from his predecessors, for he was a remarkably learned man, and to remember that he was writing a text-book, not a history of the subject.

The years 1467–71 were spent in Hungary. Here superstition was rife, and both Vitez, the immediate patron of Regiomontanus, and the king, Mathias Corvinus, had complete faith in astrology. But the man of science, for he must have been truly that, remained unperturbed On the reasonable plea that the required calculations were highly laborious in the absence of suitable mathematical tables, he produced extensive tables of the sine and tangent. Then for the necessary observations he collected for the king the finest instruments to be procured—dials, astrolabes and cross-staffs. For the most part these have been dispersed and lost, though not all. His own observations, so far as they have been preserved, were few, but others may not have survived.

So far as can be seen, the scientific outlook of Regiomontanus was always thoroughly sound. The Ptolemaic system must be understood, but he had less illusion about its nature than anyone, except perhaps Ptolemy himself. It was merely a means of calculation, and far from satisfactory at that. The lunar theory, which gave a palpably impossible range to the apparent semi-diameter of the moon, was enough to show it. But before any real advance could be made in the theory, it was necessary to recognize that the ancient observations were thoroughly inaccurate and the science must be reconstructed on a foundation of modern observations All this Regiomontanus saw and stated as clearly as Tycho could have done Therefore, when in 1471 he saw trouble brewing between his archiepiscopal patron and the king, he persuaded Mathias to allow him to establish an observatory and settled in Nuremberg with that object in view.

But once there, his activities took a completely different turn. He set up a printing press and immediately embarked on a most ambitious scheme of publication. The actual output amounted to no more than nine works, almost exactly contemporaneous with Caxton's earliest undertakings, but the details of the whole plan were announced in a catalogue here described. Moreover, some of these works presented all the difficulties of mathematical printing, with figures reproduced in the form of wood-cuts. On the technical side of this achievement it will be recalled that a generation later Dürer was at work on the same spot. But the duty of making observations was not neglected. Regiomontanus collected and installed the necessary instruments, made observations himself and, not least, trained his successor Bernhard Walther to continue this side of his work. Walther observed assiduously between 1475 and the year of his death, 1504, and his results, though published later without the care and completeness they deserved, are the most important in the long interval between the Greeks and Tycho Brahe.

But the man who had started this new epoch had vanished from the scene. He may have been summoned to Rome to advise on a revision of the calendar In 1475 he left Nuremberg and the following summer died in Rome, perhaps a victim of the plague then prevalent in the city. A tradition that he died by poison cannot be traced farther back than 1512, and though it was transmitted by Rheinhold, it is here discredited. Indeed nothing is known of this last year of his life. The printing press came to an abrupt end, and the great plans of its founder with it. As much of his work, like the instruments he assembled, has been scattered and lost, it is unusually difficult to assess the scientific importance of Regiomontanus. But this is a point to which there will be occasion to return later.

(2) The first volume of the new edition of Kepler's works has now appeared, following the third, which contained the Astronomia Nova and was published at the end of 1937. Naturally it is in the same form as the volume already noticed in the course of last year (NATURE, 141, 665 ; 1938), and it reaches the same high standard in its

presentation. The Latin text of two of Kepler's earliest works is followed by an illuminating editorial commentary in German.

All that Kepler wrote must be considered valuable as a revelation of his personality and trend of thought. But the "Mysterium Cosmographicum" (1596), a short work, is scarcely, taken by itself, an attractive one. It has two merits. The Copernican system is adjusted to a more truly heliocentric form. Also the basic conjecture, absurd as it is, is subjected to the test of careful calculations. But here at the outset of his career Kepler reveals himself as a complete scientific mystic. A copy was sent to Galileo, who returned a polite but perfunctory acknowledgment. After that he was not to be drawn into further correspondence on the subject; and little wonder, for Galileo was anything but a mystic. Perhaps this example may suggest a reason why Kepler's greater work failed to find recognition among the next generation. Like Galileo, others may have been alienated by the mystical element and may have failed to probe and find the real treasure.

The second work contained in this volume is known by the short title "De Stella Nova" (1606). The star is Nova Ophiuchi (1604), and Kepler was naturally the more interested in it because he had recently assisted Tycho Brahe in editing his observations of Nova Cassiopeiae (1572). The appearance also was the more remarkable because it occurred near a conjunction of Jupiter, Saturn and Mars. Another strange and previously unknown star had been discovered in 1600, and Kepler included an account of it as a new star; it is the variable P. Cygni, not now accepted as a *nova*.

To an ounce of science in this work there is an intolerable deal of sack. Writing with an eye on his public, Kepler must give his views on the astrological significance of the triple conjunction with characteristic verbosity. No sooner has he dealt shrewdly with one school of superstitious thought than his mysticism leads him back into equal extravagances. Of greater interest are his views on the nature of the stars. But his notions of sidereal astronomy were always completely antiquated. The ideas of Giordano Bruno filled him with horror ("nescio quid horroris") at the mere thought. Yet they had probably been picked up during a visit to England twenty years before. The essential part can be traced to Thomas Digges's work, a "Perfit Description of the Cœlestiall Orbes" (1576). The immensity of stellar space, from which Kepler recoiled, had been accepted as obvious by Copernicus.

It is now possible to return to Regiomontanus. When Mästlin undertook to produce the "Mysterium Cosmographicum" for Kepler, it seemed to him that some introduction to the ideas of the Copernican system was wanted by the uninitiated. He had the happy thought to add to Kepler's work (1596) the "Narratio Prima" (1540) of Rheticus. This tract is once again reprinted, and it is a most important document, for in the circumstances in which it was written (as an open letter addressed to J. Schöner) it must have had the approval, if not the positive inspiration, of Copernicus. The reference to Aristarchus, never made by Copernicus himself, is to be found here. The tradition was familiar to all about that time. Regiomontanus had marked "Aristarchus samius" in the margin of his copy of Archimedes, showing what was in his mind. Robert Recorde recognized the ancient source immediately. It would have been strange if the tradition, which was a perfectly explicit one, had not had its full effect on Copernicus.

There are also references to Regiomontanus, chiefly to the Epitome. But the passage which bears on his greatness runs thus:

> Principio autem statuas velim doctissime D. Schonere, hunc Virum, cujus nunc opera utor, in omni doctrinarum genere, et astronomiæ peritia Regiomontano non esse minorem; libentius autem eum cum Ptolemæo confero, non quod minorem Regiomontanum Ptolemæo aestimem, sed quia hanc felicitatem cum Ptolemæo Praeceptor meus [Copernicus] communem habet, ut institutam astronomiæ emendationem, divina adjuvante clementia, absolueret, cum Regiomontanus (heu crudelia Fata) ante columnas suas positas e vita migrarit.

The marginal note "Regiomontanus Romae veneno extinctus est An. 1476, 8. Julii, aetatis anno 40. vix completo" was supplied by Mästlin, and of course adds no weight to the earlier report of Rheinhold.

The judgment of Rheticus is valuable in itself, because he was a sensible man, with access to material and verbal traditions no longer available, and there is no reason to suspect hero-worship in this case. But more than this, it must have been endorsed by Copernicus himself, for otherwise there can have been no reason for introducing the name of Regiomontanus at all. This tribute is not to be lightly dismissed like some of the undiscriminating eulogy which has had a prejudicial effect on his reputation in later times.

The subject of Regiomontanus has been dealt with at some length in this review because in his "Planetary Systems", generally a trustworthy work, Dreyer has done far less than justice to this very remarkable man. Had he been spared another thirty years of active life, what might he not have accomplished? Heu crudelia Fata.

H. C. PLUMMER.

PLANT PHYLOGENY

Textbook of Paleobotany
By William C. Darrah. (Century Biological Series.) Pp. xii+441. (New York and London: D. Appleton-Century Co., Inc., 1939.) 25s. net.

THE publication of a short but comprehensive text-book of palæobotany in English is a noteworthy event, for great progress has been made during the last forty years in our knowledge of fossil plants, and the discoveries of the latter half of this period must eventually revolutionize many widely accepted views on evolutionary morphology. The author, who is a member of the staff of Harvard, has all the enthusiasm of youth, and has produced a book which covers a very wide field of study. The subject is treated mainly from a phylogenetic point of view, the historical evidence relating to each of the main groups of plants being considered. A few chapters are devoted to a review of the floras of the great geological epochs and to more general topics. Each chapter is accompanied by a bibliography of the more important papers, mainly from recent publications. There is a large number of illustrations which add to the interest and value of the book. Many of them are reproductions of photographs of actual specimens, though these vary in quality.

The reviewer feels considerable regret that he is unable to give an unqualified recommendation of this volume. It will certainly interest many who wish to know of the progress of palæobotany, and the descriptions of recent discoveries in the Devonian rocks will be useful to teachers. But the author of a scientific text-book has grave responsibilities. His work will provide the foundations upon which the knowledge of many students is to rest; it will largely determine their outlook on the subject. A text-book should be unimpeachable on matters of fact and should be a pattern in logical reasoning. The boundary line between objective observation and inferences drawn from the observations should be clearly discernible, so that the reader may be prepared for the changes in the interpretation of the facts which must come with new discoveries in every healthy branch of science.

From this point of view, the present work is disappointing. The author gives too little space to straight description of structures and too much to considerations of phyletic morphology. The brief mention of many of the well-known Upper Palæozoic and Mesozoic plants, sometimes little more than a catalogue of names, will scarcely allow the student to visualize their structure, and consequently the author's interpretation of their morphological significance must be accepted without question. But this interpretation may be quite speculative, or depend on the definition given to terms which are not explained. Even though a particular interpretation has been widely accepted and may be generally held at the present time, it does not follow that it is really true.

We may take as an example a reference to the Cycadales with which almost every botanist would agree. The author states that the ovules of these plants are borne laterally upon the sporophylls. "The Cycad 'carpel' is typically foliar and is a convincing example of the Phyllospermic type." But in spite of the universal repetition of this view, it cannot be said that it is based on any unquestionable evidence derived from either fossil or modern forms; until such evidence is provided, the view is just a piece of morphological dogma. It would be far better for the student and for the progress of the science to refrain from describing the seed-bearing organs of the cycads as 'carpels' and the pollen-bearing organs of the Bennettitales as 'stamens', even although these terms are placed in inverted commas.

One of the many difficulties which confront the student of fossil plants is the nomenclature used, and it is regrettable that the author did not give some indication of the international rules of palæobotanical nomenclature and classification. It may be mentioned that he has followed these rules in employing the new generic name 'Horneophyton' Barghorn and Darrah for the plant previously known as *Hornea Lignieri* Kidston and Lang. This will in future be the valid name for this important Devonian fossil, since it has been found that the name 'Hornea' was preoccupied.

Unfortunately, a considerable number of errors have got into the text and there are many very questionable statements. *Sphenophyllum fertile* is described as having the structure which Scott, with his limited material, ascribed to it. In the bibliography, however, papers by Leclercq are cited and this work, carried out by means of serial sections, showed that the cone had a very different structure. In view of the far-reaching hypotheses that have been founded on the supposition that cones actually existed having the structure described by Scott, it is surprising that the important work of Leclercq was not mentioned in the text.

In the chapter on the origin of the angiosperms, Darrah favours the view that the flowering plants originated from Cycadeoid-like ancestors. He says, "the modifications which would be required to transform the Cycadeoid flower into that of the ter flowering plants are simple ones". But, nfortunately, he stops there and does not explain hat these simple modifications would be, or what vidence he has to show that they have actually ccurred. Much of what he says about the aytoniales appears to be based on a misapprehension. He speaks of Thomas finding the greatest difficulty in demonstrating how the Caytoniales ould be the ancestors of the flowering plants, and this, like statements of other recent authors, appears o suggest that the writer of this review advocates the derivation of the flowering plants from the aytoniales, although he has repudiated it in four different publications since it was ascribed to him. As this misapprehension is finding its way into current teaching, attention must be directed to the statement made in 1930 (paper read at the Fifth International Botanical Congress 1930; *Annals of Botany*, 45, 670; 1931) and since maintained as a working hypothesis. Thomas wrote: "The flowering plants are considered to be derived from one or more groups of pteridosperms intermediate between those which gave rise to the Bennettitales and Caytoniales".

Of course, it is far easier to criticize a book of this character than to write one, and the ungracious remarks that have just been made refer mainly to the volume as a manual for students. Plant morphologists and those engaged in the study of systematic botany will find information and interest in this work as giving a modern view of the fossil evidence for plant evolution. It shows how much more we need to know and how wide is the gap still to be bridged between the lower and the higher groups of the vascular plants.

H. HAMSHAW THOMAS.

THE SCIENCE OF COLOUR

Colour in Theory and Practice
Vol. 1. General Theory. By H. D. Murray and Dr. D. A. Spencer. Pp. xvi + 176 + 3 pl. (London: Chapman and Hall, Ltd., 1939.) 25s. net.

NATURAL colour phenomena have been to a large extent accepted, rather than investigated, until fairly recent times, but our knowledge of what the dictionaries call 'chromatics' is now growing rapidly, and the word may soon lose its unfamiliar and faintly ambiguous savour. Such commercial activities as colour photography and an ever-expanding dye industry are largely responsible for the increasing colour-consciousness of to-day, and the chief stimulus to the study of colour comes from technical, rather than academic scientific, sources. The authors of "Colour in Theory and Practice" have travelled from the particular field of colour reproduction to the general consideration of colour.

But although the present volume is primarily intended as a preliminary to a survey of the applied aspects of colour, it is none the less welcome for its own sake, as a presentation of the basic facts and theories concerning the visible spectrum and its relationships with matter and mind. The authors waste no space on a historical approach to the subject, but begin with a brief résumé of present views as to the origin and nature of light, and from this pass on to an account of the ways in which a coloured or "unbalanced" visible radiation may be produced. The next short chapter, concerning the chemistry of colour, might well have been combined with the review of coloured substances which concludes the book. The consideration of the possible transformations of absorbed light energy would then follow on with uninterrupted continuity of theme. Similarly, the reviewer would have been inclined to put the relatively long chapter on practical light sources (if included in this volume of general theory at all), and the notes on light filters, before, rather than after, the account of spectrometers and spectrophotometers, and follow the latter directly with the important discussion of colour measurement and specification.

With the exception of this chapter ("The Measurement of Colour") the text is not too technical to be intelligible to the layman, and much of it, including the descriptions of the human eye, colour vision and its physiology, and the all too brief notes on colour in Nature, is very pleasantly readable. The authors are careful in their use of terms, and rightly at pains to stress the distinctions between objective and subjective concepts. The diagrams are helpful, although some indication in the graphs of the colours corresponding to various wave-lengths would be a convenience to non-physicists less familiar with the angstrom unit.

References to publications are scattered throughout the pages. The value of the work as a much-needed introduction to colour science would have been greatly augmented by a bibliography.

The book is handsomely produced, with excellent illustrations, including seven pages in colour to hearten the general reader into overcoming his fear of mathematical symbols; but its price is regrettably high.

SAMPSON CLAY.

THE LIVING BODY

A Text in Human Physiology
By Prof. Charles Herbert Best and Prof. Norman Burke Taylor. Pp. xxii + 563 + 15 plates. (London: Chapman and Hall, Ltd., 1939.) 18s. net.

A TITLE such as "The Living Body" raises the hope that this is no ordinary text-book of physiology for medical students designed for a group of readers who have already passed their first medical examination and are now studying not only physiology but also anatomy and biochemistry, on each of which they read special books. "The Living Body" suggests, and according to the authors' preface rightly so, an elementary account of how our bodies work, which includes everything, anatomy, histology, biochemistry, as well as the topics commonly included in the narrower sense of medical physiology. Only the most elementary knowledge of physics and chemistry is presupposed, and such a book might well be designed for the intelligent layman who remembers a little of the science he did at school, for nurses, and for others who are not concerned with more specialized aspects of the subject.

There may be some truth in the saying that our generation which reads avidly of the advances in physics and even biology has no interest in physiology because concern with one's body is not quite healthy or not quite proper. Yet many, not only the unhealthy or improper but also those who are healthy enough not to bother about being thought so, and those who are specifically interested in subjects such as the nutrition of the people and athletics, have been asking for a book which will tell them about the spectacular discoveries in physiology and their application to medicine which have featured in the news of the last few decades. To make these discoveries intelligible and interesting they must be accompanied by a general account of the happenings in the body. If such a demand exists, it is certain that it has not been adequately met by physiologists, who have become increasingly preoccupied with the rapid advances in their own special branches of the subject. Occasional works of genius re-fashion the shape of the subject on a wider scale, for example, Bayliss's "Principles of General Physiology" or Barcroft's "Features in the Architecture of Physiology", but these are addressed to readers who are living with the material of physiology. For the non-specialist reader some similar creative effort is needed to break away from the presentation of the subject which has become traditional in connection with the medical curriculum, to reorientate the study of the body around certain themes of immediate social urgency such as nutrition and muscular exercise, and to muster appropriately new selections of our physiological knowledge, much of it recently acquired, which might catch the imagination of the reader as a scientific adventure in exploring the functions of the body.

"The Living Body" scarcely aims so high. It professes to be elementary and dogmatic. It is elementary perhaps most noticeably in the sense that we regard anything we did in our youth as elementary, that is to say it has something of the flavour of the text-book of a generation ago, this impression being reinforced by the unusually high proportion of old friends one recognizes among the illustrations. Many instances of the danger of such a method can be found; for example, Fig. 201 showing the effect of temperature on the isotonic contraction of muscle was in its day a famous example of inappropriate apparatus yielding results which are misleading to the point of being in the opposite direction of those recorded by modern instruments. Other figures emphasize aspects of the subject which have become unfashionable because displaced by the wealth of material nearer the heart of physiology; no less than five figures, for example, depict water flowing through models consisting of rigid tubes, but the properties of the models are not to any extent used to elucidate the features of the blood circulation, the physical analysis of which is now so elaborate that the subject—hæmodynamics as it was grandiloquently called—has almost dropped out of elementary text-books.

The degree of dogmatism which is needed to make a short account of physiology clear to a reader is a hotly disputed subject, and differs according to the aims and tastes of the author. Fashion in physiology has on the whole dictated sparing use of dogmatism about disputed matters when simplicity seems to require it, but has discouraged statements appearing as facts when no evidence about the matter exists. As an example of the less fashionable view taken by the authors on the latter point may be quoted the rather unlikely value of 5 mm. given as the pressure in Bowman's capsule in the mammalian kidney.

"The Living Body" is profusely illustrated and straightforwardly written and meets the requirements of the class of reader, such as nurses and some dental and agricultural students, who requires, as the authors say, "a less scientific and more dogmatic method of instruction than that customary in more advanced texts."

F. R. WINTON.

AERONAUTICAL RESEARCH: WIND TUNNELS, OLD AND NEW

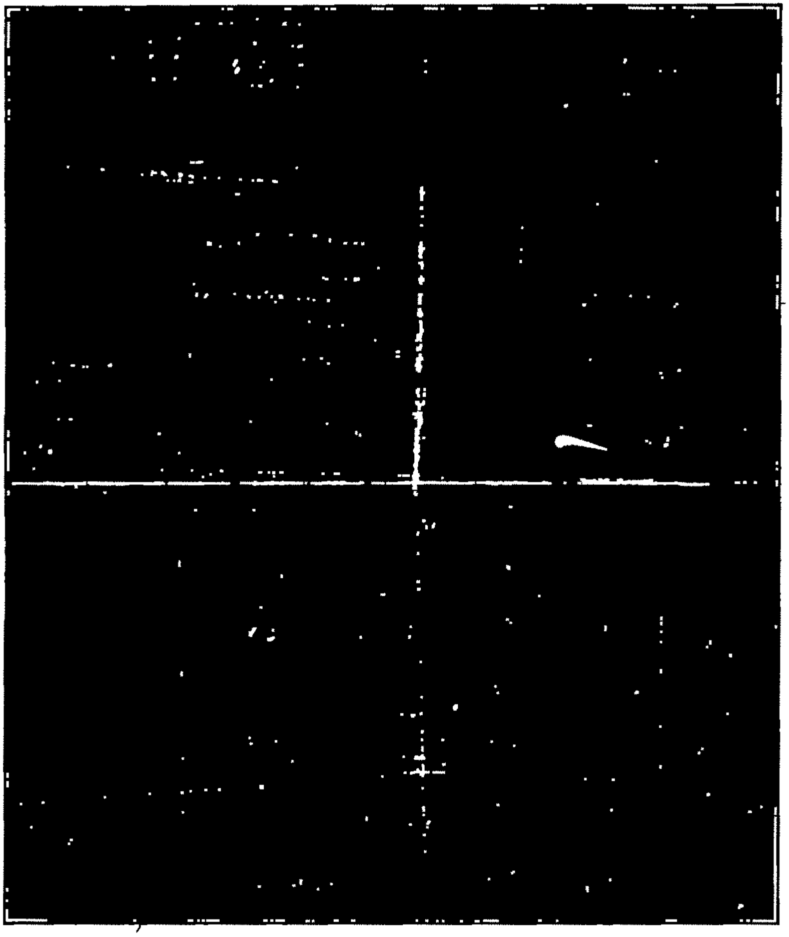

Fig. 1.
REPRODUCTION FROM THE WRIGHT BROTHERS' ORIGINAL RESEARCH PROGRAMME (1901).

R. G. W. LEWIS, director of aeronautical research, National Advisory Committee for ronautics, U.S.A., delivered the Wilbur Wright morial Lecture before the Royal Aeronautical ciety on May 25, taking as his subject "Some odern Methods of Research in the Problems of light", with some personal reminiscences of the rothers Orville and Wilbur Wright, and gave ome hitherto unpublished details of their original esearches into the problems of flight in 1901. ig. 1 shows profiles and plan forms of some of he aerofoils used by the Wrights in their wind unnel. It can be seen that models 7, 8 and 9 are ircular arcs with a systematically varied camber, nd 10, 11 and 12 have a similar camber in a more orward location; also the models have a 1-inch hord with a 6-inch span, giving an aspect ratio of 6. Research up to to-day has universally confirmed that the assumption of these forms was correct to such an extent that it almost appears to have been an extension of their original work. Since this work was never published, these later day conclusions are an independent testimony to their far-sightedness and understanding of the basic principles.

The balances used in the Wrights' wind tunnel were ingeniously contrived in such a way that the fundamentally important requirements of obtaining readings that could be translated directly into effective forces upon a full-scale flying machine were given by direct readings, having reduced their critical assumptions to one. This was that the order of merit of the various shaped aerofoils would not be seriously affected by the Reynolds

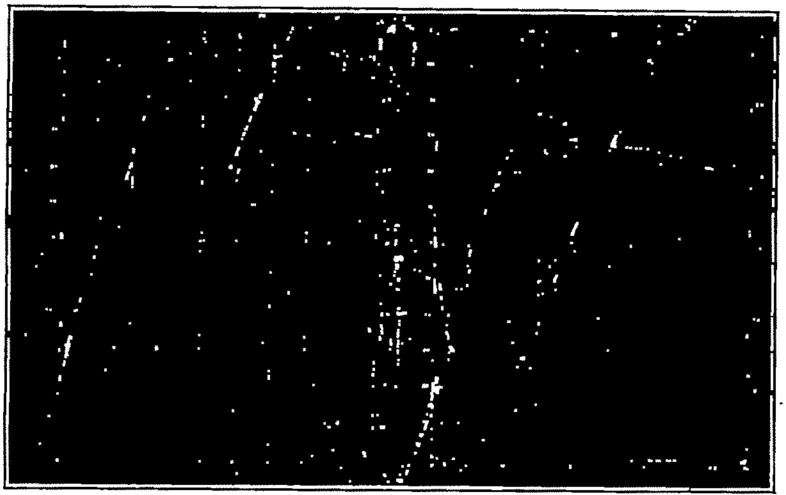

Fig. 2.

REPRODUCTION FROM ORIGINAL PLOTS OF DATA (1901).

number of the experiment, although the absolute value of the coefficients would change. An actual case is worthy of mention in this respect. The Wright brothers, combining wind tunnel results and flight tests on their 1902 glider, found that the unit drag of a square flat plate was equal to the square of the speed, in miles per hour, multiplied by the coefficient 0·0033. To-day, after considerable research directed upon this question, the figure generally adopted is 0·00328, a truly astonishing agreement.

Fig. 2 shows some results from the models 7, 8 and 9 in Fig. 1, and the familiar shape of the lift and drag curves are such that they might well apply to many aerofoil forms in use to-day.

Dr. Lewis then devoted the main part of his lecture to a description of the recent additions to the U.S.A. wind tunnels at Langley Field, the principal research station of the National Advisory Committee for Aeronautics. The general trend of improvements has been that of increase of size to allow the use of larger models, higher speed of the air stream to keep up with the increase of performance of actual aircraft, and provision for investigations at larger Reynolds numbers by the use of compressed air. Principally, the recent tunnels have been constructed with the definite object of solving the problems that arise in aeroplane design. The most outstanding of these are, the variable density wind tunnel for research at high Reynolds numbers, the 20-ft. propeller research tunnel, the full-scale tunnel, the high-speed jet tunnel for aerofoil research under propeller operating conditions, and an 8-ft. 500 mil per hour wind tunnel. The mo recent tunnel, designed in 193 and now being placed in oper tion, is shown in Fig. 3. This h a throat diameter of 19 ft., bei able to accommodate large-sca models, and works up to spee of 250 miles per hour at pressur from sub-atmospheric to sever atmospheres.

There is a general trend towar the use of dynamic models for t investigation of stability and co trol problems, based on principl adopted originally by the Aer nautical Research Committee Great Britain at Farnboroug Also certain classes of investig tions are tending towards methods, developed b Prof. B. M. Jones in England and Dryden an Jacobs in the United States, of carrying out fund mental research and applying the results by vali theoretical methods to the prediction of aircra characteristics.

The most highly specialized piece of equipmen yet constructed is the low-turbulence wind tunne designed in accordance with Eastman Jacob suggestions, and completed in the spring of 193 Turbulence and velocity fluctuation in the a stream of wind tunnels have long been a matte of concern in this work, but a helpful simplificatio is obtained from the generally accepted concep that turbulence in the atmosphere is of such nature that, in free flight conditions, its effec upon the transition from laminar to turbulent flo in the boundary layer is negligible. Tests in smok tunnels, as well as G. I. Taylor's theoretical work suggested that in low-turbulence conditions th transition point on an aerofoil might tend t

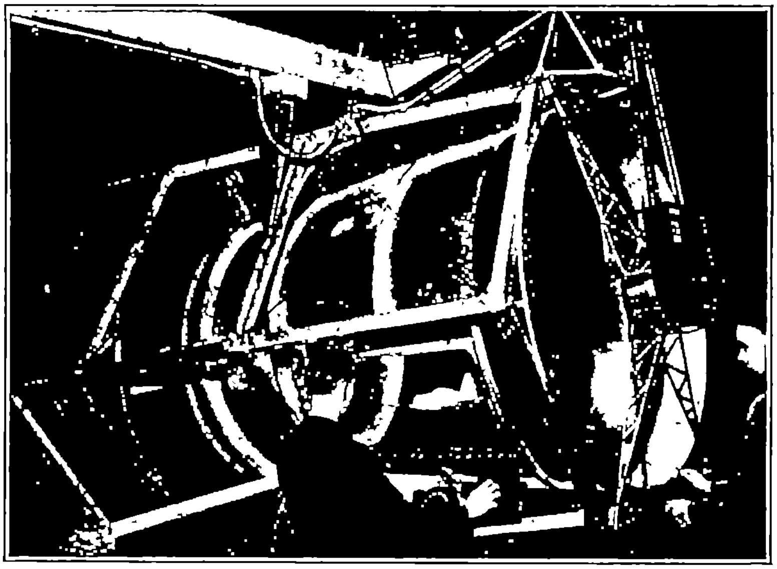

Fig. 5.
The N.A.C.A. 5-foot free-flight tunnel in operation.

main in a constant position ather than to move forward, as does in turbulent wind tunnels, nd thus an aerofoil could be degned to take advantage of true w-drag laminar boundary layers ver a major portion of its surface. is claimed that aerofoils so esigned and tested in the low-rbulence wind tunnel are showg spectacular drag reduction, hich should give valuable ineases in speed, range, and eneral efficiency of aircraft.

Another problem that has been iving increasing concern to airraft designers is that of the ynamic loading upon the strucure due to accelerations consequent upon encountering atmopheric gusts. Increase in size nd speed of the aeroplane both ccentuate this problem, and it is becoming bviously necessary to establish criteria for design gainst gust loads. The problem has been pproached from two aspects. An instrument, nown as the N.A.C.A. V-G recorder, was designed nd installed in a number of machines, the total ying time of which, to date, approximates to 7,300 aeroplane hours or 10 million miles, under s widely varying conditions of topography, eather, etc., as possible. The instrument is self-recording, needs no attention from the aircraft's crew, and gives a simultaneous recording of accelerations and air speeds. Statistical results from these instruments suggest a probable maximum effective gust velocity of about 30 feet per second for an aeroplane of the large flying boat type.

Upon this assumption, a 'gust tunnel' has been built in which it is possible to determine experimentally the reaction of suitably scaled dynamic models. It consists of an expanding rectangular channel discharging a controlled current of air in an upward direction, see Fig. 4. A weight-driven catapult launches the model into a free glide at constant speed, and when it enters the air jet it moves according to the changing forces imposed upon it. These movements are recorded photographically by light from small lamps at the nose and tail, and from these the movements of the centre of gravity and the pitching motion can be estimated. An accelerometer inside the model is synchronized with the photographic mechanism, so that the two records can be correlated.

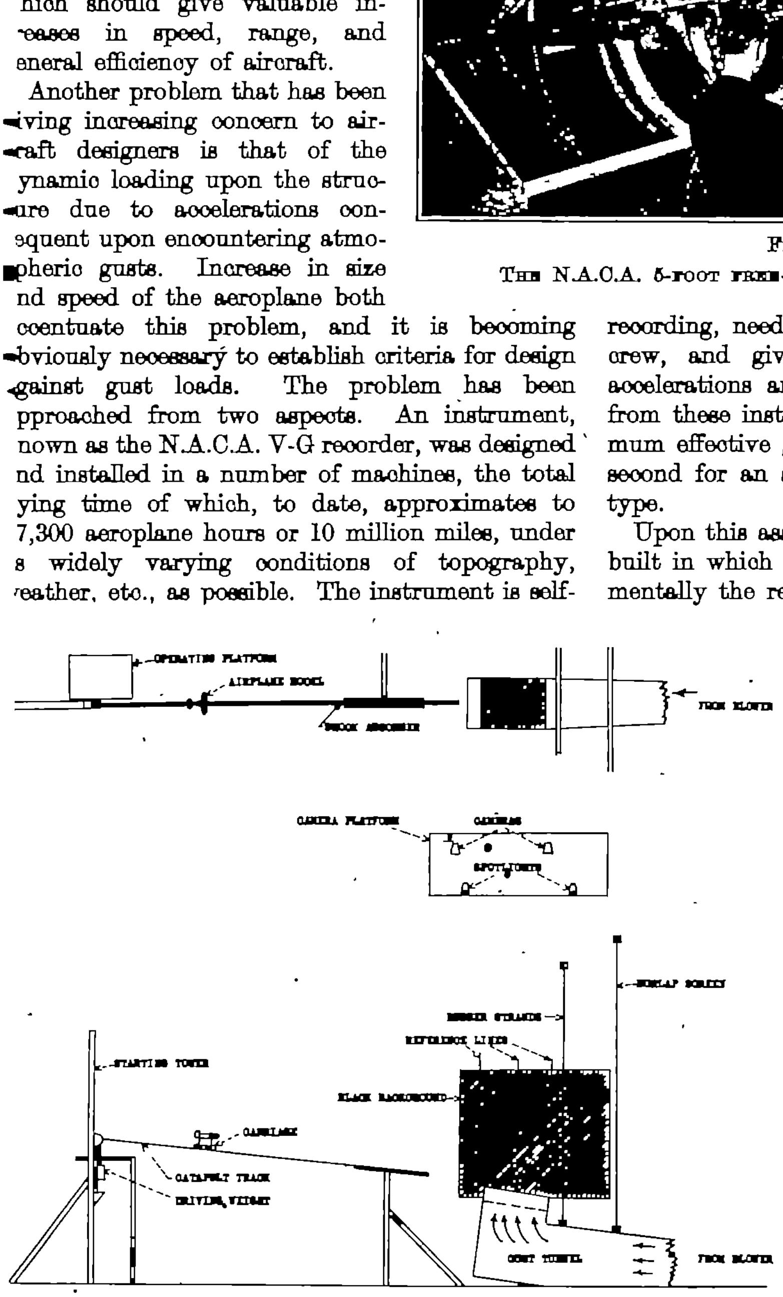

Fig. 4.
Diagram of the gust tunnel of the National Advisory Committee for Aeronautics.

The general problem of stability and control in flight is also being dealt with in a more precise manner than hitherto by means of a free-flight wind tunnel. The body of the tunnel is 5 ft. in diameter, provided with a normal fan giving air speeds up to 25 ft. per second. It is suspended on trunnions so that its inclination can be varied, and an operator maintains the inclination and air speed in proper co-ordination with the gliding characteristics of the model under test. A second operator manipulates the controls of the model, governed by small electro-magnets inside i body, by a series of switches connected the model by a fine wire of length sufficie to hang slack and allow the model perform any manœuvre unrestricted. Fig. shows this tunnel with a model in free flig inside it.

PRIESTLEY AND LAVOISIER

TWO lectures delivered by Sir Philip Hartog at University College, London, on May 9 and 16 dealt with "The Newer Views on Priestley and Lavoisier", these being given under the scheme for advanced lectures of the University of London.

It was pointed out that the usual estimates of Priestley's work are based on too little acquaintance with his writings, and do not do him sufficient justice. The work of Lavoisier is now better understood, largely by reason of the publications of the late Dr. A. N. Meldrum, and Sir Philip was concerned with some aspects of the relations between Priestley and Lavoisier.

Priestley's early work on electricity is contained in his "History of Electricity", first published in 1767 and written in a year. This shows him making quantitative experiments and putting forward hypotheses which Sir Philip Hartog thinks were based on what Priestley calls the "bold eccentric thoughts of the Queries in the Opticks" of Newton. Priestley's first thoughts on chemistry are also to be found in this book, and in it he describes some experiments on mephitic air and charcoal, the mephitic air being made by passing air over heated charcoal. After finding that a candle would not burn in air that had passed through a charcoal fire, or through the lungs of animals, Priestley says: "I was considering what kind of change it underwent, by passing through the fire, or through the lungs, etc., and whether it was not possible to restore it to its original state, by some operation or mixture". This early work provides a key to Priestley's later studies on gases, beginning with those published in 1772.

When Priestley began his work, there were three special pitfalls into which an investigator on gases could stumble, as well as the general bar to progress set by the phlogiston theory: (1) it was not known whether heat was ponderable or not, (2) it was not known whether light was ponderable or not, (3) permanent gases were regarded as essentially different from solids and liquids. Hales, in his "Vegetable Staticks" (1727), had failed to differentiate gases from air, and although Boerhaave in his "Elements of Chemistry" (1731) speaks as though he distinguished betwe the different varieties of air—including van He mont's *gas sylvestre* (carbon dioxide)—yet it w Black and Cavendish, in 1756 and 1766 respe tively, who sharply differentiated fixed air (carbo dioxide) and inflammable air (hydrogen). Priestle discovered a number of new 'airs', some of whic he collected over mercury, and his publication on these begin in 1772. The airs discovered b Priestley were stated by Sir Philip to be: hydroge chloride, nitrogen, nitric oxide, nitrous oxid nitrogen peroxide (which he collected by downwar displacement), ammonia, sulphur dioxide, silico fluoride, oxygen and hydrogen sulphide, all discovered in the period 1772–1790. After his lon paper in the *Philosophical Transactions* in 1772 Priestley published his work on gases in his books "Experiments and Observations on Different Kind of Air" (3 vols., 1774–77), "Experiments an Observations relating to various branches o Natural Philosophy with a continuation of th Observations on Air" (3 vols., 1779–86), an "Experiments and Observations on Air" (3 vols 1790). These volumes are a rich mine of experimental results.

Of Lavoisier, Sir Philip said: "From the firs Lavoisier's work is distinguished from that o Priestley and many other predecessors, not by th use of the balance as is often stated, for Priestley was quite capable of using the balance and t excellent purpose, but by the systematic use o the balance in checking chemical reactions especially in dealing with gaseous reactions". In his earlier work (November 1772), Lavoisier had discovered that in the combustion of sulphur and phosphorus, air is absorbed and the combustible increases in weight. He was also persuaded that the increase of weight of a metal during calcination is caused by absorption of air. In 1792 Lavoisier wrote: "It is easy to see that from the year 1772 I had conceived the doctrine of combustion as a whole". In February 1773 (not 1772, as Lavoisier himself, by a slip of the pen, dated his memorandum), he proposed to make a long series of experiments on gases, and in his "Opuscules hysiques et chimiques" in 1774 he fulfils this romise, both in regard to a history of the subject nd a new series of investigations. In 1774 he ad suspected that it is some *constituent* of the air, ot the whole air, which is concerned in combustion nd calcination. Although Priestley had prepared specimen of oxygen on August 1, 1774, by heating red precipitate of mercury, and observed the brilliant combustion of a candle in the gas, Sir Philip Hartog claims that the true date of Priestley's discovery of oxygen was April 1, 1775. Previous to this, Priestley had not distinguished the gas from nitrous oxide, and the crucial test distinguishing the two gases, namely, the action of nitric oxide gas, was not applied by Priestley until March 1775, and in April he speaks of oxygen as an air five or six times as good as common air".

Priestley met Lavoisier in Paris in October 1774 nd spoke of his preliminary experiments to Lavoisier and others. Lavoisier began to work n red precipitate in November 1774, and in February to March 1775 he made experiments which he communicated to the Academy of Sciences on April 26, 1775, the title of the paper printed in its first state in the May number of Rozier's "Observations sur la Physique") being: On the Nature of the Principle that Unites with Metals During their Calcination and Increases their Weight". Although Priestley had found by the nitric oxide test that the new gas (oxygen) was five times as good as common air, Lavoisier failed in this experiment and reached the erroneous conclusion that the new gas "is not one of the constituent parts of the air . . . but is the air itself, entire, unchanged, undecomposed". Lavoisier's correct interpretation of combustion and calcination was, in fact, not put forward until March 1777, when for the first time he clearly distinguished between the two constituents of atmospheric air, although his estimate of the relative proportions is again less accurate than Priestley's. Although Lavoisier does not mention Priestley in this paper, Sir Philip pointed out that he does so in other papers, and he regards the suggestion that Lavoisier made no acknowledgment to Priestley as "pure fiction". Lavoisier's mportant memoirs on combustion in general 1777), on caloric (with Laplace, 1783), and his "Reflections on Phlogiston" (1786) in which he definitely rejects the phlogiston theory, were dealt with by Sir Philip.

Priestley's views on phlogiston were of a very varying character. Sir Philip Hartog directed attention to a remarkable quantitative experiment made by Priestley in 1785. He calcined iron with a burning glass in oxygen standing over mercury, and showed that the weight gained by the iron is equal to the weight lost by the gas. He then reduced the oxide of iron by means of hydrogen and showed that the two processes can be repeated indefinitely, that the volumes of hydrogen and oxygen involved are as 2 to 1, and that the ratio of the loss of weight of the iron oxide to the weight of water formed is as 15 to 17 (actually it is 16 to 18). Although he very nearly adopted the correct explanation, Priestley says he "was taught by Mr. Watt to correct this hypothesis and to account for this result in a different manner". As Sir Philip said: "Priestley henceforward displays what seems to us almost a perverse ingenuity in adapting the phlogiston theory to fit every new fact". The later developments of the phlogiston theory have recently been studied in the publications of Partington and McKie in the *Annals of Science*, and it seems as if Priestley had been on the point of escaping from this maze but was induced to penetrate still further into it by following the lead of James Watt.

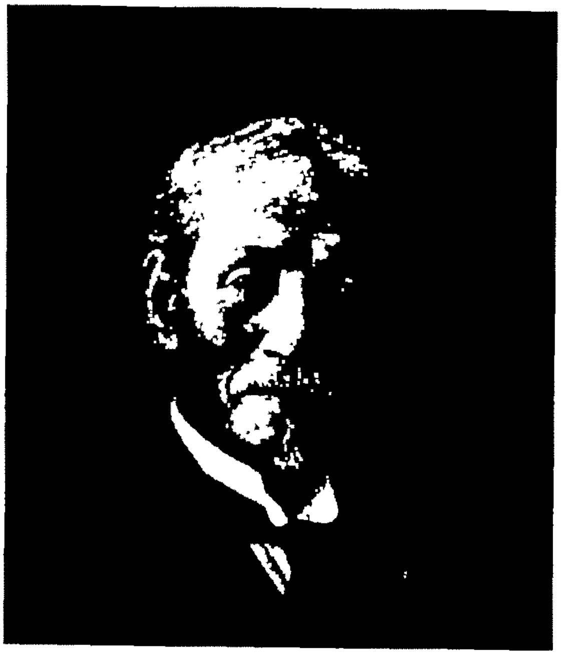
Lavoisier first enunciated his own views as a body of doctrine in his classical "Traité Elémentaire de Chimie" in 1789, a work which, according to McKie, marks the foundation of modern chemistry as securely as Newton's "Principia" marked the foundation of modern mechanics. In this book, Lavoisier lays down certain general principles of scientific method, which he had mostly taken from Condillac. Priestley had, in his earlier work, been guided by Franklin and he says: "Every experiment in which there is design, is made to ascertain some hypothesis. For an hypothesis is nothing more than a preconceived idea of an event. . . . An hypothesis absolutely verified ceases to be termed such, and is considered as a fact." Thus, science is to be reduced to a statement of all the facts in the smallest compass and the hypotheses finally disappear.

In concluding his lectures, Sir Philip said: "It may be said of Priestley and of Lavoisier individually that where a generation of chemists had been blind those two men saw. Yet neither of them was impeccable. And they had far more in common, both in their successes and their failures, than has been generally recognized, though ultimately Lavoisier outdistanced Priestley. By a combination of their discoveries Lavoisier effected a transformation of chemistry and a revelation of some of the most fundamental processes of vegetable and animal life". Although we are told that the old foundations of scientific thought are now being broken up, yet "at that earlier turning point, a century and a half ago, the pattern imagined by Lavoisier, in part with elements supplied by Priestley, was a great pattern, which served a great purpose. It multiplied man's control of external nature a thousandfold; and in itself was a vision of beauty".

OBITUARIES

Baron Joji Sakurai

ON January 28 of this year there passed away from this world, at the ripe age of eighty years, Prof. Baron Joji Sakurai, the great promoter of scientific research in Japan, ardent lover of peace and friendship among men, and one of the finest spirits and greatest gentlemen of this or any age. Proud indeed must be his homeland to have produced one who was honoured, respected, and beloved by men of science of many nations, and proud are we in England to have had him in our care during his formative years of study at University College, London (1876–1881). No one who had the privilege of meeting him ever failed to be deeply impressed and strongly attracted by his quiet dignity, his gentle and endearing modesty, and the warm glow of friendliness and high intelligence that shone from his eyes and suffused his every word. Throughout a long and laborious life he strove with a total disregard of self to make his fellow-countrymen strong and healthy in mind and body by the light of reason and science, to promote their peaceful, cultural relations with men of other lands, and to build up an amity of nations, founded on mutual co-operation directed to the high goal of a civilization, purified from ignorance and prejudice and illumined by a great hope. So lived and died this great and good man that came from the East, and was the friend of all men of goodwill throughout the world.



J. Sakurai

Joji Sakurai was born in Kanazawa (Province of Kaga) on August 18, 1858. He went to Tokyo in 1871 and studied chemistry under R. W. Atkinson at the Kaisei Gakko, a forerunner of the University of Tokyo. At the request of the Japanese Government, Atkinson had been sent to teach chemistry at Tokyo by Prof. Alexander W. Williamson, of University College, London. Williamson had early interested himself in the welfare of Japan, especially in the education of young Japanese students in England, among whom were the celebrated Prince Ito and Marquis Inoue. In 1876 young Sakurai was sent by his Government to prosecute the study of chemistry in England, and entered University College in October of that year. He studied chemistry und Prof. Williamson, physics under Prof. Carey Fost and Dr. Oliver Lodge, mineralogy under Prof. Morris, and hygiene under Prof. W. H. Corfiel At the end of his first year he won the gold med for chemistry, and a year later the Clothworker Scholarship for proficiency in chemistry and physic Under the guidance of Williamson, Sakurai began a interesting research on metallic compounds containi bivalent hydrocarbon radicals, which was continue after his return to Japan and resulted in three pape communicated to the *Journal of the Chemical Socie* in the years 1880, 188 and 1882. In 1885 h obtained methylene chlor iodide, a sign that h interest in organic chemistry still continued.

In September 1881 Sakurai returned to his nativ country and was immediately appointed lecture in chemistry in the University of Tokyo. In th following year he becam professor at the early ag of twenty-four years. A time went on, he becam deeply impressed with th importance of the nev physical chemistry associated with the names c Raoult, Le Chatelier, Arrhenius, van't Hoff, Ostwald and Nernst. By hi example and his teachin he exercised a profound influence on the direction o chemical studies in Japan and became indeed th founder of scientific chemistry in that country. Hi important modification of Beckmann's boiling-poin method for determining the molecular weights o substances in solution, an account of which appeare in 1892 in the *Journal of the Chemical Society*, was a notable contribution to the practical side of physica chemistry, whilst his work on the molecular conductivity of amidosulphonic acid (*J. Chem. Soc.* 1896) had an important bearing on the problems o molecular structure and the influence of substituen groups. In this connexion, mention must also b made of his allied investigations on the constitutio of glycocoll and its derivatives, in which he brough forward evidence for the ring- as against the usuall accepted chain-structure.

Sakurai was the founder of a great school o chemical research in Japan, many of his pupils, fo ample, Ikeda, Osaka, and Matsubara, becoming emselves university professors and leaders of emical research. He retired from his University ofessorship in 1919, having served the cause of ience and education for nearly forty years, not only inspiring teacher and investigator, but also as niversity councillor, dean of the Faculty of Science, d acting president of the University (elected norary professor soon after his retiral).

It is not possible to exaggerate the importance of e work which Sakurai did in promoting the estab-hment and development of great organizations for ientific research in Japan. Indeed, it is only fair say that the eminent position which that country cupies to-day in the world of pure and applied ience is largely due to his initiative, energy, and resight. Having been for more than thirty years fore the outbreak of the Great War one of the most tive members of the Tokyo Chemical Society, of hich he was several times elected president, the ents of 1914–18 convinced him (and others in pan) that a great development of scientific research as necessary for the well-being, prosperity and fety of that country. The first result of these forts was the establishment in 1917 of the important Institute of Physical and Chemical Research". Not ntent with this great success, Sakurai, with his lleagues and friends, worked for many years for e establishment of a national organization of much ider scope, which would have for its main object e promotion of research in *all* branches of science. he final result was that, backed by the influence nd a splendid gift of H.M. the Emperor, and pro-ided with an ample subsidy voted by the two ouses of the Imperial Diet, the Japanese Society r the Promotion of Scientific Research, with H.I.H. rince Chichibu as patron, Viscount Saito (then remier) as president, and Prof. Sakurai as chairman f the Board of Directors, came into existence in 933.

The labours involved in the accomplishment of hese great designs by no means exhaust all that akurai did for his country and for science. He was lected president of the National Research Council f Japan soon after the international conferences eld in 1918 in London and Paris, and retained this osition until his death. He attended, as the leader f the Japanese delegation, the second Pan-Pacific cience Congress, held in Australia in 1923, and at he third Congress, in Tokyo in 1926, prepared, as hairman of the International Committee, a draft onstitution and by-laws for the permanent organiza-ion of the Congress. These were adopted with only light verbal alterations, and the Pan-Pacific Science ssociation came into existence.

Prof. Sakurai attended, as the scientific represen-ative of his country, very many international meet-ngs and congresses. His dignified bearing, clear-ighted wisdom, and charming personality became in his way widely known to men of science of many ations. He was twice elected a vice-president of he International Chemical Union, namely, in 1923 nd 1928, and at the third general assembly of the International Council of Scientific Unions (London, 1937), was elected a vice-president, filling the vacancy created by the death of Marconi.

Many honours came to Sakurai from foreign countries. Thus he received the honorary degree of LL.D. from the University of Glasgow in 1901, and was elected an honorary member of the Chemical Society of France, the Society of Chemical Industry, the Royal Institution of Great Britain, the American Chemical Society, the Academy of Sciences of the U.S.S.R., and the Chemical Society of Poland. In 1931 he was elected an honorary fellow of the Chemical Society, and in 1937 an honorary fellow of University College, London. This very high distinction from his old *alma mater* gave him particular pleasure.

It was natural and just that the great and meritorious services which he rendered to his country were signalized by distinguished honours: Order of the First Class of the Sacred Treasure (1916); appointed by the throne a member of the House of Peers (1920) and Privy Councillor (1926); Grand Cordon of the Rising Sun (1929). Shortly before his death he received the Grand Cordon of the Rising Sun and Paulownia, and was created a baron*.

Owing to the old connexion of University College, London, with Prof. Sakurai and with the development of the Empire of Japan as one of the scientific great powers of the world, I had the privilege of welcoming to the Chemical Department of University College a number of Japanese men of science, including many Ramsay Scholars, amongst whom may be mentioned K. Matsuno, K. Suzuki, R. Azuma, H. Tsukamoto, Y. Hori, N. Kameyama, K. Kodama, R. Sato, S. Takagi, Y. Yamaguchi, M. Emi, R. Shinoda, Y. Nagai, T. Somiya, I. Sawai, R. Tsuchida, R. Matsuda, N. Ando, and H. Oosaka. The pleasant and friendly association with these young men, many if not all of whom now occupy important positions in their own country, was a very happy experience in my life; and to have been able to contribute to the preservation of a long and faithful friendship an especial joy.

The name of Joji Sakurai will live in the history of science and civilization. As a great patriot, his name will shine in the history of his country. Joji Sakurai, the man, lives as a fragrant memory in the minds of his host of friends.

F. G. DONNAN.

---

* I am deeply indebted to Prof. Koichi Matsubara for much of the biographical information embodied in this notice.

Prof. M. V. Shuleikin

SOVIET science has suffered a great loss in the death on July 17 of Prof. M. V. Shuleikin, member of the Academy of Sciences of the U.S.S.R. and chief engineer of the Department of Communications of the Red Army.

Prof. Shuleiken spent thirty years of strenuous work in the preparation of numerous scientific workers in the field of radio-communications and in the development of Soviet radio-technics. He commenced his scientific and teaching career in 1908 after graduating from the St. Petersburg Polytechnical Institute. Soon after the Revolution he removed to Moscow, where he worked in the Red Army on the development of military communications. As a result of this work he was successful in solving many complex problems; he produced numerous valuable works dealing with the strengthening of the country's defence capacity. At the same time, Prof. Shuleikin was engaged in extensive educational work. He gave all the principal courses in radio-technics at the former Moscow Higher Technical School, at the Military Electro-Technical Academy, at the Institute of National Economy and at the Moscow Electro-Technical Institute of Communications.

The last six years of Prof. Shuleikin's activities were closely connected with the Academy of Sciences of the U.S.S.R. In 1933 he organized the work at the Academy relating to electro-communications. Under his guidance this work helped to solve a number of problems connected with the diffusion of radio waves, the maintenance of regular communications on the main radio services, and also the adoption of measures to combat magnetic storms.

Prof. Shuleiken was elected a member of the Academy of Sciences of the U.S.S.R. at the beginning of this year. He threw himself with still greater energy into the work of solving the complex problems relating to modern radio-technics and the working out of material for a general plan of development of communications in the Third Five-Year Plan. He also took part in the building of the Palace of Soviets in Moscow, in the capacity of chief consultant on questions relating to communications.

Mr. F. W. Jones, O.B.E.

MR. F. W. JONES, well known for his work in small-arm ballistics, died at a London nursing home on June 25. He was a native of Nottingham but received his training (1887–89) at the Royal College of Science, South Kensington. On leaving college, he joined Colonel Schultze's factory in the New Forest, where the first smokeless shotgun powder, 'Schultze granulated gunpowder', was in its initial stage of development. Within two years, Jones became the manager of the factory and he was thus one of the earliest pioneers of the smokeless powder industry.

Shortly afterwards, Jones joined the Smokeless Powder Company, Ltd., at the works at Barwick, Hertfordshire, and in the following year became works manager. At this factory colloidal nitrocellulose powders were first manufactured in Great Britain, and a wide series of 'rifleites' was prepared for military and sporting use. In 1898, Jones was the principal witness for the defence in a long and important action brought by Heidemann against the Company for infringement. Although the Company won the action, it was crippled financially and soon passed into liquidation.

Jones then became a consultant on explosives. His early clients included Eley Bros., New Explosives Co., Ltd., Cogswell and Harrison, and the *Field* newspaper, and he was also 'proof master' to the London Proof House. At this time he advanced considerab the science of ballistics, both in rifles and shotgun and published many articles on this subject in *Arm and Explosives.* A large portion of his work w incorporated in the "Service Textbook of 1929" a justifies his title as the greatest small arms ballistici in Great Britain.

Jones was not only pre-eminent in the theory rifle shooting, but also at the target, using the matc rifle. At his first visit to Bisley some twenty-eigh years ago, he was the winner of the aggregates, on to lose the prize because the barrel of his Ross rif was slightly overweight. His successes at Bisley hav continued regularly ever since, and last year, seventy-one years of age, he won the first three the match rifle competitions. He was generally on of the first selections for the English team. H worked indefatigably after the Great War for th production of a British military cartridge firing nitro cellulose powder and a streamline bullet, and he live just long enough to see this cartridge, largely th result of his own personal labours, adopted by th British Government. His successes at Bisley wer most popular, since his advice and great experienc were always at the service of those who desired them

During the Great War, Jones rendered assistanc to the Ministry of Munitions in the large field experimental and research work found necessary i meeting ever-changing war conditions. Developmen of caps and tracer and armour-piercing rifle bullet were some of the most important items.

After the War, on the concentration in Imperi Chemical Industries of the manufacture of powde and ammunition, Jones was appointed technic adviser, and his services were invaluable in assistin the improvements and developments in powder an cartridges.

WE regret to announce the following deaths:

Dr. Vladimir Brandstätter, who has collaborate with Prof. Absolon, curator of the Moravian Museum in extensive local archæological excavations, o July 18, aged forty years.

Dr. Alfred Harker, F.R.S., emeritus reader i petrology in the University of Cambridge, on July 28 aged eighty years.

Prof. W. P. Lombard, emeritus professor of physiology in the University of Michigan, on July 13, age eighty-four years.

Prof. J. H. McFadden, assistant professor o psychology in the University of Pittsburgh, o May 28, aged forty years.

Dr. W. J. Mayo, co-founder with his brother, th late Dr. C. H. Mayo (see NATURE of July 15, p. 103) of the Mayo Clinic, Rochester, Minnesota, on July 28 aged seventy-eight years.

Prof. R. W. Reid, emeritus regius professor o anatomy in the University of Aberdeen, on July 28

Mr. Scoresby Routledge, known for his investigations among the Akikuyu of East Africa and of th archæology and ethnology of Easter Island, o July 31, in his eightieth year.

NEWS AND VIEWS

ir George Stapledon, C.B.E., F.R.S.

All who are interested in the progress of agricultural science and practice will hear with great atisfaction that the Royal Agricultural Society has warded its Gold Medal to Sir George Stapledon, professor of agricultural botany and director of the Welsh Plant Breeding Station, Aberystwyth, for his conspicuous services to agriculture. This follows losely on the knighthood recently conferred upon him and on his election into the Royal Society, and the triple recognition of the good work he has long done for agriculture during a very strenuous life is xtremely gratifying. Sir George began his agriultural career at Cirencester, where he early became interested in grassland problems and laid the foundaions for the special studies that he has since brilliantly developed. When the plant breeding station was established at Aberystwyth he was put in charge of it and commenced work on the breeding and selection of grasses, clovers and oats. He did not confine himself to the experimental fields, but also undertook wider investigations in grassland management which were greatly developed when the magnificent donation of Sir Julien Cahn enabled the College authorities to acquire a hill farm. In the course of his activities, he has visited Australia and New Zealand and studied grass problems there. At present he is making a survey of the grasslands of Great Britain, and those who have read his books will look forward with interest to the account which it may be hoped will be published when his review is complete. His many friends wish him many years of continued fruitful activity.

Dr. David Fairchild

Dr. David Fairchild, veteran plant explorer of he United States Department of Agriculture, has been awarded the Meyer Medal of the American Genetic Association for distinguished services in plant introduction at the Glendale, Maryland, Plant ntroduction Station of the United States Department of Agriculture. Dr. Fairchild has been associated with the U.S. Department of Agriculture or fifty years. Through his unflagging interest and enthusiasm, hundreds of new plants have been introduced into America. From this work has grown the date industry in California. The soybean, another ntroduction resulting from Dr. Fairchild's work, is now an industry worth seventy million dollars. Many of the superior cereals now grown on American farms owe their resistance to disease and their ability to withstand unfavourable weather conditions o plant introductions which have been used in breeding work. A most important recent incident in plant introduction has been the saving of the cantaloupe industry in California which was decimated some years ago by a fungus disease, powdery mildew. A wild variety from India, itself of such poor quality as to be scarcely edible, was found to be resistant to the mildew. This resistance has been transferred by applied genetic method to excellent new varieties, also resistant. Dr. Fairchild joined the U.S. Department of Agriculture in July 1889, fifty years ago. He established, and was for many years head of, the office of Foreign Seed and Plant Introduction. During this time he travelled widely through all parts of the world. In 1938 he retired from active service with the Department, but his interest in plants has remained, and in the years following his retirement he has been instrumental in much work with new plants now being carried on in Florida, where he has lived since his retirement.

Prof. Jaroslav Perner

Prof. Jaroslav Perner, professor of palæontology in the Charles University, Prague, has recently celebrated his seventieth birthday. He was born at Týnce on the Labe (Elbe) in 1869 and studied zoology and palæontology under Profs. Antonin Frič and Otokar Novák. He acted as assistant and later as keeper of the Geological Department at the National Museum, where his chief work was the arranging of Barrande's collections. After Barrande's death, Prof. Perner continued his great treatise "Systême Silurian du centre de la Bohême". He described the Gastropoda of the formations included in the system, in three quarto volumes, during the years 1903–1911. Before this, Perner had published four volumes of his important treatise "Études sur les Graptolites de la Bohême" (in Czech) wherein he corrected the old and incorrect accounts of this fauna and laid the basis for the modern stratigraphic division of the Lower Palæozoic rocks of Bohemia. After the death of Prof. E. Koken of Tübingen in 1912, the Russian Imperial Academy of Science at St. Petersburg asked Mr. Perner to continue Koken's "Gastropoden des baltischen Untersilurs". This Perner did during 1913–1925. In addition he has written a number of scientific articles on Phyllocarida, trilobites, fishes, conodonts and other fossils of the Palæozoic rocks of his country. These have appeared mainly in the *Journal of the Bohemian Academy of Sciences* or in the *Centralblatt für Geologie*. On the death of Prof. Filip Počta in 1928, Prof. Perner was appointed professor of palæontology in the Charles University, and had control of the palæontological collections at the Geological Institute (under Prof. Radim Kettner). He obtained part of the great Hanus collection, which contained much new and rare material. A new development of his subject has taken place since his appointment, which can be seen from the published work of his pupils. He is a corresponding member of the Palæontological Society of Washington, a member of the Bohemian Academy of Arts and Sciences, and an honorary member of the Bohemian Royal Society of Sciences.

Close Approach of Mars

MARS was in opposition with the sun on July 23, and was nearest the earth, at a distance of 36 million miles and with an angular diameter of 24·1″, on July 28. Despite the closeness of the approach, the apparition is a most unfavourable one for observation in high northern latitudes. This is because of the planet's very large south declination. In May its declination ranged between −22½° and −23°; by the end of June it increased to −24°; and it is now −27°. Thus, since observations began, the altitude above the horizon in the latitude of Greenwich has never exceeded 16° and is now less than 12°. It follows that observers in Great Britain and in most northern observatories cannot expect to get good views of the planet during the present apparition. We shall have to rely almost entirely for our results on observers in the southern hemisphere. Astronomers in northern latitudes may look forward confidently to the next apparition in 1941; for then the planet will be high in their skies and not very much farther away from the earth. During the present apparition, the southern hemisphere of Mars is tilted towards the earth, the latitude of the centre of the disk being −12° at the beginning of June and −7° at the end of August. The spring equinox of Mars' southern hemisphere occurred on June 1; the summer solstice will occur on October 24.

IN addition to the disadvantage of the planet's low altitude, English observers have had to contend with exceptionally bad weather conditions. The long spell of unsettled weather has brought with it very poor definition, which is, of course, greatly exaggerated when observations have to be made near the horizon. On the few clear nights available, Mars has generally resembled a pulsating ball of wool; and only on rare occasions, and then for brief intervals, has the disk been steady enough for the more prominent features to be made out. The south polar cap which up to the beginning of July was large is now starting to melt rapidly. The southern *maria* have in general appeared fairly dark and many of the lighter regions situated in their midst have appeared shaded over. This phenomenon has been particularly striking in certain regions. Thus the Rev. T. E. R. Phillips observed Hellas deeply shaded; and during the last two weeks Dr. R. L. Waterfield found the region *south following* the *Solis Lacus* to be much darker than usual: But the *Solis Lacus* itself, so far as one could see, presented its normal configuration, and had not undergone any such striking metamorphosis as it presented in 1926 and 1928. There have been remarkable whitenesses towards the north polar regions, which about July 10 and July 30 were almost as dazzling as the southern snow cap. These may be due to cloud, although their brilliance suggests that they are snow; but if they are due to snow, they are probably not part of the pole-cap proper, as they are situated very eccentrically with regard to the north pole itself. It is gratifying to hear that Dr. V. M. Slipper of the Lowell Observatory has gone to Bloemfontein to observe the planet. So far, no official reports have come to hand; but according to brief reports in th Press he has already detected some interesti changes in the *Solis Lacus* region, which are possib those referred to above.

Official Tests of 'Anderson' Shelters

A SERIES of official tests was recently carried o on the 'Anderson' air raid shelter, and the resul published. The A.R.P. Co-ordinating Committe which is an independent body of architects, surveyo medical men and men of science under the chairma ship of Prof. J. B. S. Haldane, has made some serio criticisms of these tests in a statement forwarded Sir John Anderson. The Committee admits that certain amount of useful information has bee obtained, but it considers that insufficient tests we carried out to justify what it calls 'far too optimisti conclusions. A number of interesting points a raised; for example, the Committee thinks that is not enough to do each explosion test once only and if, as is claimed, apparently similar bombs ofte behave differently in exploding, the objection woul seem to be justified. The Committee also asks f further research into the physiological effects blast, a subject which is very imperfectly understoo It is well known that 'blast' is, in effect, a very rapi rise in pressure followed by a slightly slower fall. is this *rapid* fluctuation of pressure, presumabl which gives blast its lethal effect. The Committe rightly points out that there is strong evidence tha it is not the *magnitude* of the changes in pressur which matters so much as the rate at which th pressure changes. The reactions of the human bod to fairly slow changes of pressure have long bee well known to physiologists, but there is little exa knowledge of the results to be expected when th body is subjected to wide fluctuations in a fractio of a second. If, as we are told, the general populatio is to be exposed to just such changes, the Committe would seem to be justified in calling for more researc

THE Committee's statement raises the furthe point that the tests indicate that in many Londo boroughs the population, if sheltered entirely i Anderson shelters, might be expected to suffe approximately seventeen casualties per ton of bomb dropped, and says, "When it is borne in mind tha the President of the Air Raid Protection Institut estimated in March 1939, that Germany alone coul despatch 3,000 tons of bombs per day to this country the seriousness of the position will be apparent" The Committee urges that this is further reinforce ment for the case for a scheme of heavily protecte shelters, particularly in fairly densely populate areas, and argues that if the tests had preceded th adoption of the official shelter policy a differen policy might well have been adopted.

Saxon Time Measurement

IN making a clearance of earth during alteration to the Cloister Garth at Canterbury Cathedral Saxon pocket sun-dial, or time-piece, of gold an silver was found recently at a depth of two fee below the surface. It is described (*The Times*, Jul 31) as being in the form of a tablet of silver with a gol ap and chain, and for gnomon a gold pin surmounted by a delicately chased animal head, with jewelled eyes and a ball in its mouth. This pin, when not in use, rested in a hole at the lower end of the tablet, and was in this position when the time-piece was found. On the faces of the tablet are inscribed the names of the months, abbreviated and in pairs. At the top of each of the three columns is a hole for the pin when in use, and below each hole two spots. Of hese the higher in each month, when the dial hangs free, indicates noon and the lower 9 a.m. and 3 p.m. marking the hours of the monks' services. Along the edges runs the inscription: *Pax Possessori—Salus Factori*. The dial has been tested for accuracy by Dr. A. H. Smith of University College, London. The grouping of the months in pairs according to their equivalent distances from the summer solstice s based, it is to be presumed, on the table given by Bede for measuring the shadow of a six-foot gnomon. Dr. Smith finds that owing to its small size, the dial would only be approximately accurate. It would, however, be more or less correct at noon in latitude 53° N. at the middle of certain months, or early in others, while in the far north of England it would be more or less accurate through the summer months. At 9 a.m. and 3 p.m. it would be more or less accurate in late January, mid-February, mid-March, early April, early May, late July, mid-September, early October, early November and early December.

Anglo-Saxon Ship Burial

Ship burials are of sufficient rarity, even on the Continent, for the discovery of an Anglo-Saxon ship burial at Sutton Hoo, near Ipswich (*The Times*, July 26, July 31) to be regarded as a memorable and, indeed, remarkable event. This is, in fact, only the second of the kind to be found in England, a previous discovery, though of a rather less impressive character, having been made at Snape, two miles away. In the present instance, the vessel in which he interment had taken place was a rowing galley 82 ft. long. The quantity and character of the jewellery and other personal objects associated with the burial were such as to justify the assumption that a chief lay buried here. The personal relics were found collected together in the centre of the ship, and included a handsome gold buckle, clasps and fastenings of the garments, gold studs from a belt, and small plaques of gold bearing figures of human beings and animals. The sword had been laid by the side of the body; but it has almost entirely perished, with the exception of the richly ornamented gold and jewelled pommel. The deceased had also been provided with money, the remains of a purse being found beside some coins. Other articles found with the burial were iron pots and spearheads, and an object which has the appearance of a sceptre, having faces carved at either end. A metal cup may, it is thought, have contained some articles of symbolic significance. The grave is situated on the estate of Mrs. E. M. Pretty, and has been excavated by the authorities of the Ipswich Museum, under the field direction of Mr. Guy Maynard, with the co-operation of H.M. Office of Works and the British Museum.

Lightning Flashes and High Tension Mains

During July there were many violent thunderstorms and much damage was done to overhead electric mains and substations connected with them. The damage done to main stations was also severe. On July 19, a violent thunderstorm cut off Valley Road Power Station at Bradford from the Grid and shut down all the generating sets there. For about an hour, mills, factories, trams and trolley-buses on many routes came to a standstill; the traffic lights failed and there was no light anywhere for about an hour. A similar occurrence took place at the Brighton Power House at Southwick. In both cases the difficulties of the staff were increased as they were engaged in changing over on the Grid supply from 6·6 kilovolt to 33 kilovolt. There was a heavy storm over Cumberland and the overhead transmission was struck. This affected the supply to more than 30,000 houses in Cockermouth, Maryport, Aspatria and Wigton as well as part of Workington, the lights being out from 3.15 p.m. to 8.30 p.m. On July 19, at 8 p.m., the B.B.C. National Transmitter at Droitwich was struck by lightning and put out of action. The flashes striking the 700-ft. masts of the Radio Station were extremely violent. Flames shot from the cage of aerial wires slung between the masts. In some places transformers or switchgear were damaged and three fires broke out, destroying substation roofs or walls. Since thunderstorms are less frequent in Great Britain than in South Africa and other parts of the world it might be useful to study the effects of modern lightning protectors in protecting poles, steel towers, overhead mains, etc., in places where thunderstorms are frequent and violent. Also when designing new grids or extensions of old ones to get estimates of the relative costs of overhead mains and of underground mains. A decision could then be arrived at as to which is the better method of transmitting high-tension electric power.

Empire Broadcasts on Scientific Topics

The British Broadcasting Corporation has instituted a short series of quarter-hour broadcasts to the Empire on recent advances in science. The first talk of the series was given at 11.15 p.m. on July 31 by Prof. Allan Ferguson, one of the general secretaries of the British Association. Prof. Ferguson, after giving a simple picture of the structure of the atom, and the results to be expected from atomic bombardment, described briefly the development of the cyclotron, recent experiments on nuclear disintegration, including the uranium-fission experiments, and the production of 'labelled' particles. Succeeding talks will be given by Wing-Commander Cave-Browne-Cave on mechanical engineering (August 7), by Dr. S. J. F. Philpott on psychology (August 14) and by Prof. F. A. E. Crew on biology (August 21).

League of Nations

"The League from Year to Year (1938)", which has recently been issued by the Information Section of the Secretariat of the League of Nations, contains the usual concise account of the year's activities in sufficient detail to facilitate careful study of the political, legal and technical work of the various organs of the League of Nations. (Geneva: League of Nations; London: George Allen and Unwin, Ltd., 1939. Pp. 214. 1*s*.). Of special interest to scientific workers are the chapters on intellectual co-operation, the health organization, the communications and transit organization and those on the European conference on rural life and technical collaboration with China. A chapter dealing with refugees is included as well as one on mandates. The detailed chronological table of the principal events in the League's sphere of activity during the year, giving the dates of the meetings of the different organs of the League and of their principal decisions, as well as of world political events affecting the League's work introduced last year for the first time is again a feature of the new edition.

The Colonial Problem

THE proposals of the Labour and Peace movements for dealing with the colonial question are examined in a pamphlet "New Tendencies in Colonial Policy" issued by the Pacifist Research Bureau (New Tendencies in Colonial Policy. With an Introduction by Leonard Barnes. Pp. 16. London: Pacifist Research Bureau, 1939. 2*d*.). It is argued that there are only two alternatives: an extended and re-arranged imperialism with new rival imperialisms of greater equality and an ultimate clash between them; or the removal of existing imperialisms and their substitution by a great conception of civilization's responsibility for the so-called uncivilized, with an equally great conception of world economic organization. The necessity of conforming to the wishes, or, at least, obtaining the consent of the native peoples in all matters affecting their welfare is also emphasized, including the application of this principle not only to the mandated territories but also in other colonial questions. The problem is further discussed in another pamphlet issued by the Bureau, "War and the Colonies" (War and the Colonies: a Policy for Socialists and Pacifists. Pp. 16. London: Pacifist Research Bureau, 1939. 2*d*.), in which proposals for a world conference to effect the liquidation of imperialism are briefly outlined.

Language in Science

THE general considerations of linguistics which throw light upon the procedure of science are discussed by L. Bloomfield in the fourth number of volume one of the "International Encyclopedia of Unified Science" (Linguistic Aspects of Science. By Leonard Bloomfield. Pp. viii+60. (Chicago: University of Chicago Press; London: Cambridge University Press, 1939.) 5*s*. net.). If language is taken into account, science can be distinguished from other phases of human activity by agreeing that science shall deal only with events that are accessible in their time and place to any and all observers or only with events that are placed in co-ordinates of time and space, or that science shall employ only such initial statements and predictions as lead to definite handling operations o only terms such as are derivable by strict definition from a set of everyday terms concerning physica happenings.

IT is the task of science to provide a system o responses which are independent of the habit of any person or community, but Mr. Bloomfield points out how far short we are of accurat definition in regard to meanings which are involve in the habits of communities and individuals, sinc the relevant branches of science are quite undeveloped. Discussing the development of scientific language he distinguishes between the informal and forma scientific discourse, and emphasizes the importanc of defining exactly the meaning of technical term and limiting their use within the agreements upon which they are based. When meanings of the outsid world are admitted, error may be incurred an certainty is lost. With regard to the place of linguistic in the scheme of science Mr. Bloomfield places i between biology and ethnology, sociology an psychology. It stands between physical and cultura anthropology. It is closely related to logic, sinc it observes how people conduct a certain type o discourse. The critique and theory of scientific speech is the task of logic. Mathematics, however, is a science only so long as we believe that the mathematician is not creating speech-forms and discourse (which is a skill, craft, or art) but exploring a unknown realm of concepts or ideas.

Library Services in the United States

UNDER the title "Professional Library Education" the Office of Education, United States Department of the Interior, has issued a bulletin by Nora E Beust (*Bull.* No. 23; 1937) describing the present position of library services in the United States and indicating the possibilities it offers as a career, and the qualifications required for the various fields o service. Much that is said of the different types of library such as the public library, the school, the university or the special library is true generally, and if due allowance is made for the different conditions and details in the United States, this pamphlet gives a reasonably sound guide to the possibilities in Great Britain also, even if some directions have been much more developed in the United States. Details regarding training for librarianship, like the figures showing the present status of the profession, relate solely to the United States and attention is directed to a marked growth in the number of librarians in the last three decades, particularly in comparison with the number of practitioners in other professions. Some reasons for success and failure in library work which are set forth in conclusion are of general validity.

The Society of Applied Biologists

PRIOR to the year 1904 there was no scientific society or journal in the United Kingdom devoted to applied biology. There was, moreover, little opportunity or encouragement for research in this field, and the work of the universities and other ucational institutions was primarily concerned with ure science. Owing to the initiative of Mr. W. E. llinge of the University of Birmingham and others, owever, the Society of Applied Biologists (as it is ow termed) came into being. And as 1938 marked e publication of the twenty-fifth volume of its urnal (*Annals of Applied Biology*), Prof. W. Brierley, int editor since 1921, has written an interesting ccount of the development of the Association (*Ann. pp. Biol.*, 26, 178; 1939), correlating it with more eneral trends of development in the country over e same period of years. From the outset the Society as welcomed all investigators in economic biology, hether agricultural, horticultural, medical or com- ercial, and since its inception has steadily widened s interests. The journal, too, has increased in scientific alue, developing from a volume of 359 pages in 922 to one of 891 pages in 1938. The inclusion of hotographs of the presidents of the Association om 1904 up to the present time adds much to the nterest of the retrospect.

gricultural Research Institutes

THE reports on the work of the agricultural research nstitutes in the United Kingdom carried out during e year ending September 1936 have now been pub- shed (London: H.M. Stationery Office. 5*s*.). The olume also includes reports of a number of other nvestigations, particularly into animal diseases, set foot by the Agricultural Research Council, and ccounts of the research activities of the agricultural dvisory officers. Those who require fuller informa- ion on any subject are invited to consult the original apers, a list of which is attached to each report, or to nquire of the director of the institution concerned. armers and others in need of advice on agricultural r horticultural matters are reminded that by apply- ng to the agricultural organizer for their county, they an draw direct benefit from these research and dvisory services. It is perhaps unfortunate that so much delay occurs before these reports are published, s thereby some of their value is inevitably lost.

Know Your School" Movement in the United States

To the various agencies which foster local interest n the public schools of the United States, such as the fficial popular magazine *School Life* and parents' ssociations, a notable addition has recently been ade. At the request of the American Association f University Women, the Office of Education pre- ared a series of study outlines of certain aspects of he public school system for the use of the Associa- ion's branches. These proved so widely acceptable hat they are being reprinted as ten-page leaflets. hose already issued are: "Know your Board of ducation" (Local Education Authority), "Know our Superintendent", "Know your School Principal" nd "Know your Teacher". They deal simply and learly with such questions as "What are the duties f the principal?", "What should be his qualifica- ions?", "Relationship to the local education author- ty, to the superintendent, to supervisors, to teachers, o the school janitor, to the community". They are well adapted for guiding discussion by study circles and contain suggestions for investigation and discussion. In an article by the president of the University of Chicago which appeared in *The Times* United States Supplement of June 8, reference is made to "the deep and abiding faith of the people in education", and it concludes—"we shall yet make good our boast that we are giving the world a demonstration of education by and for democracy". The leaflets should serve as an acid test of this faith, and eventually tend to strengthen it.

Manufacture of Rare Gases

IN an article by H. C. A. Holleman on the manufacture of rare gases (*Philips Tech. Rev.*, May), a method is described by which rare gases, as well as oxygen and nitrogen are obtained from the air at the Philips' factories at Eindhoven in Holland. During the Great War, when it became more and more difficult to import the argon necessary for filling the incandescent lamps made in the factory, they were forced to manufacture the gas itself and a gas liquefaction plant was installed. This plant continued to grow steadily after the War, as it was found to supply many needs. So many different gases, all of which can be obtained from liquid air, are used in the Philips' factories that it was very important to have the whole manufacture under one control. Besides argon, which is used for filling electric lamps, the rare gases helium and neon are also used in gas discharge tubes. For glass blowing and in the machine shops large quantities of oxygen are used in order to reach higher combustion temperatures than it is possible to reach with air. Liquid oxygen and nitrogen are both used on a large scale for cooling purposes and as aids in obtaining a high vacuum.

As a protective gas in the working of metal parts for electric lamps and radio valves, much use is made of a mixture of nitrogen and hydrogen. Nitrogen is also used during the manufacture of electric lamps as a washing gas, while it is also used to fill special kinds of lamps. A modern installation for the separation of air by the Linde method is described. Since krypton and xenon have relatively high boiling points, they collect in the liquid container below the main column, which contains oxygen for the most part. Methane occurs in variable amounts in the air and has about the same boiling point as krypton, so that it is collected with the krypton in the liquid oxygen. This leads to difficulties in practice since liquid oxygen together with a combustible substance like methane can easily form an explosive mixture and lead to accidents. Hence the strictest precautions have to be taken in the preparation of krypton and xenon.

Earthquakes registered at De Bilt during 1936

THE "Seismische Registrierungen in De Bilt", 24; 1936, published in November 1938 and written by Dr. G. Van Dijk with a foreword by Dr. H. G. Cannegieter, contains a description of the instruments in use at the station with the constants necessary for the interpretation of the seismograms obtained, a list of the abbreviations used, acknowledgments, a short paragraph on microseisms together with a table, followed by fifty-three pages in small clear type of the earthquakes recorded. This record contains details of 443 earthquakes, giving in each case the date, phase and time of recording, the period of the phase, direction of initial impulse and remarks. The remarks consist chiefly of amplitudes, epicentre, and readings obtained by other observers who have communicated with De Bilt. A very sound practice has been not to give the recorded time of every prominent pulse but to limit the identifications to *P*, *PP*, *PPP*, *S*, *SS*, *SSS*, *L*, and *M* phases, so presenting very valuable data for seismological research in many directions.

Diploma in Fuel and Refractory Materials at Leeds

FOR many years past the University of Leeds has provided courses for post-graduate students leading to special diplomas both in gas engineering and in fuel and metallurgy. A one-year course leading to a post-graduate diploma in fuel and refractory materials has now been arranged, in order to meet the growing demand for men with special training in refractory materials. Commencing in October next, the new course will be given in the Department of Coal Gas and Fuel Industries, and will be additional to the normal instruction in the subject received by all students reading for degrees in gas engineering and in fuel and metallurgy. An approved degree in science or technology is required as a preliminary qualification; and the subsequent specialized training in fuel and refractory materials is intended as preparation for entry into either the 'manufacturer' or 'user' sides of the refractories or allied industries. Particulars of these courses may be obtained from the Registrar of the University.

Announcements

THE following awards of the Royal College of Physicians have recently been made: the Moxon Gold Medal to Sir Arthur Hurst, senior physician to Guy's Hospital, for his researches and observations in clinical medicine; the Baly Gold Medal to Prof. C. H. Best, professor of physiology in the University of Toronto, for his physiological researches; the Weber-Parkes Medal and Prize to Sir Pendrill Varrier-Jones, founder and medical director of the Papworth Village Settlement, for his work on tuberculosis at the Settlement.

THE Council of the City and Guilds of London Institute has conferred the distinction of fellow of the Institute upon the following: Mr. L. B. Atkinson, Mr. C. R. Fairey, Mr. E. Fawssett, Dr. L. F. Goodwin, Sir Follett Holt, Sir Gilbert T. Morgan, Mr. F. Handley Page, Sir Leonard Pearce.

A TEAK memorial seat to the late Sir William Perkin, the chemist, is to be unveiled and dedicated to the public at Sudbury, Middlesex, on August 12. The memorial will be outside a recreation ground, and opposite the site where Sir William's house and laboratory stood. The cost of the memorial has been met by public subscription.

DR. GWENVRON M. GRIFFITHS has been appoint to the Kathleen Schlesinger research fellowship f the year 1939–40. The fellowship is provided fro a fund established by the late Mr. Eugen M. Schl inger and Mrs. Schlesinger in memory of th daughter, and is given for investigations of cysts the brain or allied conditions. It is ordinari tenable at the National Hospital for Diseases of t Nervous System, Queen Square, London.

PROF. THEODOR VAHLEN, president of the Prussi Academy of Sciences, has been awarded the Goeth Medal for Art and Science by the German Chancello

THE Medical Research Council has appointed D Donald Hunter, physician to the London Hospita and Mr. Harold E. Clay, national secretary of th Passenger Services Group, Transport and Gener Workers' Union, to be members of the Industri Health Research Board, in succession to Prof. J. Nixon and Mr. R. Coppock.

MR. E. J. LUDLOW of Brylls, Waltham S Lawrence, Berks, has been awarded the Founde Company fellowship to commence in Septemb next. Mr. Ludlow will be the first person to hol this fellowship, which has been recently create The normal value of the fellowship is £250 a yea and will be renewable for a second year and in speci cases for a third year.

MR. PAUL VELLACOTT, headmaster of Harrow, ha been elected master of Peterhouse, Cambridge, i succession to the late Prof. H. W. V. Temperley.

THE fourth International Congress for Racia Hygiene will be held in Vienna on August 26–2 under the presidency of Prof. E. Rudin. The fee i 10 marks. Further information can be had from th Office of the Congress, Einemstrasse 11, Berlin, W.6

IN NATURE of March 25, p. 515, it was stated tha the University of Peiping has been reopened unde the direction of Prof. Hisomu Nagat, formerly of th University of Formosa. Monlin Chiang, writing a chancellor of the National University of Peking states that the National University is now in Kunming, Yunnan, as part of the National Southwester Associated University. He says that, following th fall of the city on July 29, 1937, all the nationa universities in Peiping moved with their facultie and staffs and almost 90 per cent of their students leaving behind them practically all their books an apparatus, to the interior and combined into severa groups under new names, of which the Nationa Southwestern Associated University is one. As th evacuation took place during the summer vacation these universities were able to reopen in their nev homes more or less according to their origina academic calendars, with what little equipmen they had secured in the short interval.

ERRATUM.—In NATURE of July 22, p. 150, th dates for the Congress of the International Unio against Tuberculosis were incorrectly given a August 11–September 20. They should rea September 16–20.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 251.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Expression of Vacuolar Sap

RECENT work carried out here supports some, but, re think, not all of the views recently expressed by hillis and Mason[1] regarding the composition and tructure of cytoplasmic and vacuolar saps in plants. opper beech leaves which contain anthocyan in the acuoles of epidermal and palisade tissues were used nd were carefully pressed between flat plates in the 0-ton testing machine of the Engineering Department through the kindness of Prof. C. H. Bulleid. are was taken to avoid slipping of the leaves as uggested by Phillis and Mason.

Juice exudes when the leaves are pressed. Increase n pressure above approximately 400–500 atmospheres loes not result in expression of any further appreciable uantities of juice from the leaves when alive and ninjured. If this residue is killed by freezing in olid carbon dioxide a considerable further amount f juice is expressed at these relatively low pressures s described by Phillis and Mason. Data regarding he samples of juice in a typical experiment are given n the accompanying table:

	Before killing			After killing
Pressure applied normal to leaf surface (atmos.) ..	133	230	350	350
Osmotic pressure of expressed juice (atmos.) ..	8	11	11·5	24
Volume of juice per 100 gm. leaf (ml.)	9·5	7·7	2·2	10·1
Colour of juice in Lovibond units per cm. depth—				
Red units ..	22	20	—	10
+ Yellow units ..	22	19	—	6
+ Blue units ..	30	24	—	2
Mean plasmolytic value in atmospheres—epidermis	24			
mesophyll	30–35			

It will be noted that the juice expressed before illing was strongly coloured by anthocyan. In fact, t contained 80 per cent of the total anthocyan. The uice obtained after killing contained little anthocyan nd had an osmotic pressure two to three times reater than the juice obtained before killing. It is ifficult to escape from the conclusion previously rawn by Phillis and Mason that the first pressing xpressed vacuolar sap (of low osmotic pressure) and he second, after killing, expressed cytoplasmic sap. he distribution of anthocyan in the samples rules ut the suggestion that the low osmotic pressure of he alleged vacuolar sap is due to filtration of water rom the solutes which remain behind.

With a different technique, it is possible to bring bout this filtration and compare the two processes. n the experiment just described the pressure was uickly applied, that is, the pressure rose from zero o 133 atmos. in the space of about five minutes. n the 'slow pressure' treatment leaves are subjected o, say, 25 atmos. for about thirty minutes, by which ime all the juice expressible at that pressure will ave exuded. The pressure is raised at first by 5 atmos., later by about 10 atmos. increments until no further juice is obtained; after each increment the system is allowed to come to equilibrium before the next increment is given. The juice so obtained is colourless and tends towards pure water in composition. In our experiments its osmotic pressure has varied from 1–4 atmos. Finally, when the residue from this treatment is killed by carbon dioxide freezing and pressed, a further quantity of juice is obtained which is strongly coloured by anthocyan and has the very high osmotic pressure of 30–37 atmos. The explanation is that the slow pressure treatment has squeezed out the vacuolar water, leaving the solutes behind, and when the tissue is killed and pressed the juice obtained contains the cytoplasmic water and solutes and the vacuolar solutes also.

With the slow pressure treatment no liquid is obtained at all below about 23–25 atmos. and only traces at this pressure; but in the pressure range 30–50 atmos. about half the expressible liquid is obtained (it should be emphasized that it exudes very slowly, as indeed it exudes very slowly during plasmolysis). When one recalls that the plasmolytic value for the epidermis of these leaves is about 23–25 atmos. this result is very significant and strongly suggests that this figure (the plasmolytic value) actually represents the hydrostatic pressure within the cell.

To conclude, our view is that when a relatively large pressure is suddenly applied, as in the quick-pressure treatment, weak parts of the liquid protoplast are distended and fissures are formed through which the vacuolar liquid is forced. Phillis and Mason suggested expression of vacuoles through fissures without making clear whether they regard these fissures as being produced by sudden application of pressure. When the slow pressure treatment is applied, bursting in this manner does not occur and filtration of water through the semi-permeable protoplast takes place, resulting in a concentrating of the vacuole exactly similar to the concentrating of the vacuole which occurs during plasmolysis. The anthocyan distribution and osmotic pressure data show, we believe, that the vacuolar sap of these leaves has an osmotic pressure of about 8–11 atmos., that the hydrostatic pressure within the cells is about 25–35 atmos. (in the several tissues), and that the difference is attributable to secretory work done by the living protoplasts[2].

Liberation of Potassium by Acetylcholine in the Central Nervous System

SIMILARITIES in the physiological activities of potassium and acetylcholine have been frequently pointed out[1]. As we know that potassium directly affects the functions of the cells, one should consider whether acetylcholine works through a liberation of ionic potassium or not. This might be the case, as in such organs like muscles and the central nervous system a combined form of potassium has been actually detected. Consequently, the liberation of potassium under the influence of acetylcholine was the first thing to look for.

As an object for our inquiry, we took the central nervous system of the Hungarian Esculenta. The whole nervous system was carefully isolated and cut into two homologous longitudinal portions. Both were soaked in isotonic saline (1 c.c.), one being kept for a control, the other being submitted to the action of the drug. After a while (about one hour), nervous tissue and surrounding saline were treated in a mortar in a final concentration of 96 per cent alcohol, and free, uncombined potassium was estimated in the liquid after centrifuging. The following data have been gathered:

(1) Neither eserine alone nor acetylcholine alone affected the content of free potassium.

(2) Acetylcholine, when eserine had been previously supplied for thirty minutes, increased the ratio of free potassium (12–56 per cent, with an average of 23 per cent).

(3) A previous treatment with atropine inhibits the effect of acetylcholine.

Thus it is demonstrated that acetylcholine liberates potassium from some compound. Considering our experimental conditions are purposely unphysiological in the sense that nervous cells turn rapidly inactive in the absence of oxygen, it is highly probable that the effect of acetylcholine should not be considered as the consequence of a functional alteration due to it, but rather to its primary and direct effect.

What adrenaline would do under the same circumstances is now the matter of our investigations.

Influence of Sodium Chloride on Glucose Absorption from the Intestine of Iodoacetate-poisoned Rats

IODOACETATE poisoning decreases the rate of absorption of glucose and the 'actively absorbed' hexoses from the intestine of rats by about 60 per cent, whereas the absorption of xylose is not affected by this poison[1]. Adrenalectomy has the same effect on sugar absorption[2]. According to Meyerhof[3], iodoacetate acts on glycolysis by suppression of the oxido-reduction between pyruvic acid and triosephosphate. It has been suggested[4] that adrenalectomy influences the glycolytic metabolism in a similar way. Now it has been shown by various American workers that adrenalectomy is followed by a severe disturbance in the excretion and distribution of electrolytes, and that by means of a diet containing no potassium and much sodium it is possible to maintain life with adrenalectomized animals indefinitely. It was ther fore tried whether the effect of iodoacetate on sug absorption also depends on the electrolyte compo tion.

Female rats of 150–200 gm. were used. Six hou before the absorption experiment they were give subcutaneously 1·5 c.c. 1 per cent NaCl + 0·5 c. N/10 Na_2CO_3. Two hours before the absorption th dose was repeated and 1½ hours before the absorptic the animals were poisoned with 0·1–0·12 mgr iodoacetate 1 gm. body weight. The experimen were carried out in urethane narcosis using the san methods as in the above-mentioned previous work Simultaneously with the sugar, a third dose of sodiu chloride (0·5 c.c. 1 per cent subcutaneously) w given. The experiments showed indeed that th inhibiting effect of iodoacetate on sugar absorptic is suppressed after sodium chloride administratio The accompanying table shows the experimental dat (including experiments in which Na_2CO_3 was replace by NaCl, and which show the same type of result

AMOUNT OF GLUCOSE ABSORBED IN 45 MINUTES (PER CENT OF TOT AMOUNT INJECTED).

Normal rats	Iodoacetate-poisoned rats		
	Without NaCl	After NaCl + Na_2CO_3 administration	After NaCl administration
83·5	26·0	62·0	73·0
49·3	25·0	75·5	63·2
72·6	28·0	73·0	65·5
62·8	31·0	69·0	81·5
61·5	31·0	58·0	
Average: 65·9	28·2	67·5	70·8

The general toxic effect of iodoacetate on rats i counteracted by sodium chloride in a similar way Female rats of 90–110 gm. die 12–16 hours afte injection of 0·05 mgm. iodoacetate/gm. body weigh whereas after administration of sodium chloride in similar dose as above they survive after a dose 0·08 mgm./gm.

Nicotinic Acid, Pentose-nucleotides and Anæmia

IN a recent issue of NATURE[1], Caspersson an Schultz stress the importance of the occurrence o pentose-nucleotides in the nucleus and especially i the cytoplasm of cells in rapid mitotic division. Thei observations would appear to have a distinct bearin on the subject of the pathogenesis of perniciou anæmia and other blood abnormalities of kindre mode of origin.

Some time ago[2], the suggestion was made that, i these conditions, the normal formation of erythrocyte by the mitotic division and subsequent ripening o the erythroblast was in abeyance: and that the re blood cells were here formed, heteroplastically an directly, from the corresponding hæmocytoblast (primitive or definitive as the case might be) afte multiplication had occurred by an amitotic process

In support of this hypothesis, it was found[3] in the ase of a major sequela of iron deficiency in the pig vhich was characterized, among other appearances, y great destruction of liver parenchyma and a nacrocytic anæmia, that the administration of liver xtract produced a dramatic amelioration in which here took place a return of the circulating blood to ormality and a replacement of the amitotic hæmocytoblastic blood formation in the marrow by a nitotic erythroblastic one. Recently Elvehjem and is collaborators[4] have shown that liver extract conains nicotinamide, a substance which, as is well mown, constitutes with pentose-nucleotide the oenzyme system. Further, Chick and co-workers[5] ave demonstrated that nicotinic acid brings about rapid restoration of health in a condition of the pig ermed by them "pellagra", but which, failing vidence to the contrary being forthcoming, would ppear to be the iron deficiency sequela.

Casperson and Schultz emphasize the point that n rapidly growing embryonic tissues (with frequent nitotic division, therefore) the cytoplasm of the cells tains basophile, an occurrence which they attribute o the presence of nucleotides. The characteristic eature of the hæmocytoblast is intense basophilia f the cytoplasm with marked achromasia of the ucleus. This state of affairs, on the contrary, is not ssociated with mitosis, rapid or otherwise, but with mitotic division, a process recognized by the cometent authorities as being, in the majority of cases, degenerative one. The degenerative aspect of the ase is further added to by the fact that ripening f the erythrocyte, whether directly, as here, from he hæmocytoblast or indirectly, as in normal conlitions, from the erythroblast, is essentially a legeneration.

In these circumstances it does not appear to be mreasonable to assume that, in mitotic division onditions with rapid increase in the chromatin of he dividing nuclei, nicotinic acid is a necessary djunct to the nucleotides in the formation of oenzyme for the carrying out of important intraellular functions such as mitosis must be. Its absence vould seem to furnish an explanation of the deenerative amitosis, defective chromatin formation, nd premature ripening of the erythrocytes in the onditions just considered, in that coenzyme would e unable to function without it: while the return o normality in such cases after its administration ould be construed as a restoration of the activity f the coenzyme by its presence.

On these lines it would seem that a tentative nderstanding of the pathogenesis of the anæmic onditions under discussion could be arrived at, hough it is not suggested that nicotinic acid is the ole agent in liver extract which is active in such ircumstances. At the same time, it is not supposed hat failure of mitotic division in such cases is limited o the cells of the hæmopoietic system.

Preliminary Investigation of the Metabolism of Stilbene

EXPERIMENTS on the recovery of synthetic œstrogenic compounds related to stilbene and diphenylethane[1] from the urine of female rabbits have shown that the recoveries are very high compared with that of œstrone under the same conditions[2]. Compounds such as 4 : 4′-dihydroxy-γ : δ-diphenyl-*n*-hexane and 4 : 4′-dihydroxy-α : β-diethylstilbene give recoveries of the order of 20 per cent compared with 1·5 per cent found for œstrone. This indicates a metabolic process for the synthetic œstrogens different from that of œstrone.

In studying the metabolism of these compounds, it was considered of importance to include stilbene, the simplest related active compound, which has been shown to produce full œstrous response in ovariectomized rats when injected in doses of 25 milligrams[3].

Two grams of stilbene were injected into two female rabbits over a period of twenty days, and from the urine a crystalline phenol, melting at 283° C., was isolated. No depression in melting point was observed on mixing with an authentic specimen of 4 : 4′-dihydroxystilbene, melting point 284° C. No *p*-hydroxybenzoic acid was isolated from the urine, but benzoic acid was found in such quantities, more than twice that found in the control rabbit urine, as to leave little doubt that benzoic acid is a metabolic product of stilbene.

It is of particular interest to note that 4 : 4′-dihydroxystilbene is a more active œstrogen than stilbene, as it produces full œstrous response in doses of 10 milligrams, and 60 per cent response in doses of 5 milligrams, when injected into ovariectomized rats[4].

Further extensive work on this subject is now in progress.

Vaginal Smears and the Œstrous Cycle of the Cat and the Lioness

A STUDY of vaginal smears taken from ten cats during a period of a year showed that their œstrous cycle consists of the following four chief phases:

(1) *Pro-œstrus.* Characterized by the presence of very numerous nucleated epithelial cells, of fairly uniform shape.

(2) *Œstrus.* The picture obtained is variable, being apparently dependent on the individual intensity of the reaction[1]. Thus in the spring large, flat, non-nucleated cornified cells predominate, together with a smaller number of nucleated cells of similar shape. The proportion of nucleated to non-nucleated cells is reversed during shorter seasons of lower temperature, such as autumn. It should be noted that these are not the only cellular elements of the œstrous smears; smaller, intensely staining round cells, with distinct nuclei, being also encountered

sporadically. The appearance of these uncornified cells may be ascribed to irregular cornification of the vaginal epithelium, as was shown by histological preparations in which differently shaped and non-cornified cells could be observed in the folds of the vagina. The diagnosis of the phase of the œstrous cycle thus depends not only on the presence of characteristic elements but also on their mutual proportions. Thus, the presence of sporadic leucocytes does not exclude œstrus. We would add that the œstrous smears also contain fairly numerous, free deformed nuclei.

(3) *Metœstrus* in the cat is, as in the other animals, characterized by the appearance of masses of leucocytes in the smears. The leucocytes are also evident in histological preparations of the vaginal wall, showing that their appearance is not due to irritation involved in taking smears.

(4) *Anœstrus*. Various types of nucleated epithelial cells, differing in size, shape, and affinity to stains, both of the plasma and the nucleus, are found in anœstrus. The relative proportions of these various cells are neither characteristic nor constant.

Smears were taken from two lionesses in œstrus and anœstrus. During the resting period the smears contained various types of epithelial cells, as in the case of the cat. The œstrous smears contained preponderatingly large, flat, non-nucleated, cornified cells, with a smaller number of cells containing pyknotic nuclei. Here also free deformed nuclei were found. Similar results were obtained for occasionally taken œstrous smears in the wild polecat. Only sporadically were epithelial cells of other types encountered.

It may, on the basis of our findings, be stated that the vaginal smears of the cat and the lioness are practically identical, and may be used for the diagnosis of the phase of the œstrous cycle; the most characteristic is the smear obtained during œstrus.

Δ 3,5-Cholestadiene from Cholesteryl Oleate and its Possible Bearing upon the Formation of Carcinogenic Substances in Heated Fats

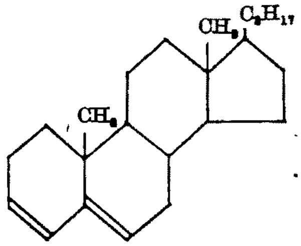
In recent years, several research workers have studied the problem, whether cancer of the skin in the tropics could be caused by carcinogenic substances formed in the skin after strong irradiation and whether the high percentage of cancer of the stomach in northern regions was connected with the usual diet and its preparation (for example, heating of fats). In a number of communications, Roffo[1] has proved the carcinogenic action by the ultra-violet rays of sunlight, and his results have been corroborated by other authors[2]. He has put forward, too, the theory[3] that a carcinogenic substance may be formed by the action of ultra-violet rays from cholesterine, which accumulates in the skin under the influence of the irradiation. Roffo has tried to strengthen this view by experiments *in vitro* with cholesterine; however, a definite reaction product has not yet been isolated and, moreover, the chemical evidence given is not convincing[4].

Concerning cancer of the stomach, Waterman[5] added heated fats or an extract of them to the diet of mice and observed consequently papillomas of the stomach, in some cases with ulceration. Administration of cholesteryl oleate produced similar results, even of greater malignity[6].

According to Roffo[7], oral administration of irradiated cholesterine, irradiated egg-yolk, or several fats boiled for thirty minutes causes neoplastic alterations of the alimentary tract of mice.

Recently, Domagk[8] in some cases obtained tumours of the stomach in mice fed on a diet rich in olive oil, while Widmark[9] concludes from his experiments that extracts of roasted food (horse muscle treated at 275° C., browned butter and roasted coffee) contain one or more carcinogenic substances. In collaboration with Dr. Waterman, we have attacked the problem from the chemical side by trying first to isolate an active substance from heated fats, secondly studying the pyrolytic decomposition of cholesteryl oleate as a type of cholesteryl ethers, which occur normally in fats. In the latter case, one may expect[10] the formation of an unsaturated steroid hydrocarbon, related to those studied by Staveley and Bergmann[11] "in order to discover whether the presence of any particular number and arrangement of double bonds would produce carcinogenicity in steroids" and to Δ 2,4-cholestadiene, the photo-oxide of which has been studied by Butenandt and Kudfuss[12] upon carcinogenic activity in tarring experiments.

Therefore synthetic cholesteryl oleate (British Drug Houses) was distilled *in vacuo* (0·3 mm., bath-temperature 300–340° C.). From the distillate a hydrocarbon $C_{27}H_{44}$ was isolated with m.p. 77–78° C. and $\alpha_{D} = -114°$. (Analysis $C_{27}H_{44}$: C. 87·96, H. 12·04. Found C. 87·68, H. 11·89.) From this evidence we conclude that we are dealing with Δ 3,5-cholestadiene[11].



The reaction with but one molecule of bromine, indicating that the two double bonds present are located in two different rings, and the absorption spectrum* with maxima at 228, 235 and 243 mμ confirm this opinion.

In feeding experiments with this hydrocarbon in a group of mice during a year, Dr. Waterman[13] obtained four papillomas of the stomach, one of which showed infiltrating properties. Though these experiments are to be continued for a longer time and on a larger scale, it seems to be very probable that a carcinogenic hydrocarbon may be formed from a cholesterine ether occurring in fats. With regard to this property, other cholesterine ethers are being examined.

The isolation of Δ 3,5-cholestadiene[14] from *irradiated* cholesteryl acetate, which substance otherwise n be distilled without decomposition, possibly forms linkage between the thermal decomposition of a olesterine derivative examined and the changes ought about by irradiation in Roffo's experiments. so, the irradiation experiments carried out *in tro* with free cholesterine should be extended to olesterine ethers.

---

* I am greatly indebted to Prof. L. S. Ornstein and co-workers, Utrecht, for measuring this and other absorption spectra.

Still in another way these facts are linked together, nsidered in connexion with the results of a recent vestigation by Waterman[14], who, studying carcino- nic hydrocarbons polarographically, found that any of them, and also △ 3,5-cholestadiene and radiated cholesteryl oleate, showed a reduction terval at 350 mv, while cholesterine, irradiated or ot, did not possess this property.

From later experiments[15] it appeared that the nsaponifiable matter of heated fat, freed to a large ctent from sterols, showed the same reduction henomenon and that the similar fraction from nheated fat did not do so.

Synthetic cholesteryl oleate in higher concentra- ons than formerly used also gives the same interval ccording to the mode of preparation the presence f traces of △ 3,5-cholestadiene may be expected !).

The details of this investigation, together with the sults of feeding experiments by Dr. Waterman, will e published elsewhere.

Constitution of Solasonine (Solanine-*s*)

FURTHER analyses of the gluco-alkaloid, solasonine olanine-*s*), the aglycone, solasodine (solanidine-*s*) nd its derivatives are in agreement more with the olecular formulæ, $C_{45}H_{73}O_{16}N$, for the glycone and $_{27}H_{43}O_2N$ for the aglycone. Formulæ, $C_{27}H_{45}O_2N$ nd $C_{26}H_{43}O_2N$, for the aglycone and corresponding rmulæ for the gluco-alkaloid are not yet excluded ut are less likely on theoretical grounds. From iochemical considerations a formula containing 27 rbon atoms is also to be preferred since there are o well-authenticated steroid derivatives, with the ception of solanocapsine and solanocapsidine[1] to hich the same argument may apply, containing 3 carbon atoms. Since solasonine gives rise to uose, galactose, rhamnose and solasodine on hydrolysis[2], it must now be built up from these sugars and one molecule of the aglycone and not two as suggested by Oddo.

According to Oddo and his co-workers, solasodine contains two active hydrogens (Zerewitinoff) and forms an amorphous diacetyl derivative (a crystalline monoacetyl derivative has now been obtained, m.p. 195°, which is soluble in dilute acids). Since it gives with nitrous acid a crystalline compound richer in nitrogen, Oddo concluded, on the basis of a formula, $C_{18}H_{31}ON$, that solasodine contains both a hydroxyl and a secondary amino group.

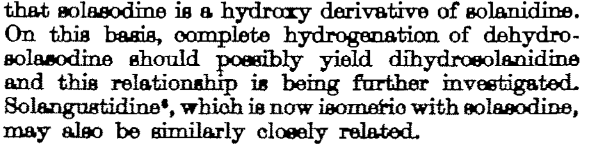
When the compound formed by nitrous acid is crystallized from alcohol containing a little ammonia, however, pure solasodine is regenerated indicating its salt-like character. Also, solasodine yields quaternary salts by simple addition [methiodide, m.p. 286° (decomp.), ethiodide, m.p. 284° (decomp.)] so that it is a tertiary base. A Zeisel estimation shows the absence of an NCH_3 group so that the nitrogen probably forms part of two rings.

Consequently, both oxygens must be present as hydroxyl groups (Zerewitinoff) and since only a monoacetyl derivative is formed, the second hydroxyl group is probably tertiary. Dehydration by means of methyl alcoholic hydrogen chloride removes one hydroxyl forming dehydrosolasodine, identical with 'solanidine-*s* ether'[2] and 'solanosodine'[3] and the same compound has also been isolated from the mother liquors during the purification of solasodine (cf. Rochelmeyer[3]).

On selenium dehydrogenation, methylcyclopentenophenanthrene and pyrrole bases are produced[4] indicating a steroid structure. It gives a digitonide[5] thus placing one hydroxyl group in *cis* position on C_3.

Solasodine forms a hydroderivative on catalytic hydrogenation and a dibromo derivative by addition. It must therefore contain one double bond, provisionally placed on analogy with other steroids at C_5—C_6.

On the above evidence and assuming a cholesterol carbon skeleton and one point of attachment of the basic portion to the steroid nucleus, the structure of solasodine is most probably



The same conclusion has been reached by Clemo, Morgan and Raper[6] for the basic structure of solanidine which is very similar in its chemical reactions to solasodine. It would appear therefore that solasodine is a hydroxy derivative of solanidine. On this basis, complete hydrogenation of dehydrosolasodine should possibly yield dihydrosolanidine and this relationship is being further investigated. Solangustidine[6], which is now isomeric with solasodine, may also be similarly closely related.

Both solasodine and solanidine give a series of beautiful colour reactions with *p*-substituted aldehydes and acetic-sulphuric acid, indicative of a pyrrolidine rather than a piperidine type of compound.

With R. Culford Bell, the alkaloid purapurine[7] from the fruit of *Solanum aviculare* has now been shown to be identical with solasonine, while a more detailed examination of the alkaloid from *S.*

auriculatum[8] has shown that it is not identical with solasonine.

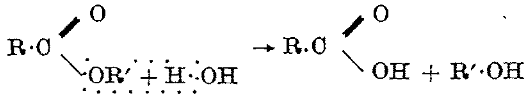
Mechanism of Hydrolysis of Inorganic Esters

BY the use of water containing an excess over the normal of the heavy oxygen isotope (^{18}O), it has been definitely and very directly shown that during the hydrolysis of the esters of weak carboxylic acids the break occurs at the C—O bond of the ester, thus:



$$R\cdot C\begin{matrix}\diagup O\\ \diagdown OR'\end{matrix} + H\cdot OH \rightarrow R\cdot C\begin{matrix}\diagup O\\ \diagdown OH\end{matrix} + R'\cdot OH$$

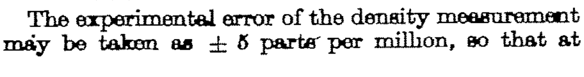
Thus the alcohol resulting from the hydrolysis contains only the normal proportion of heavy oxygen isotope. This has been shown by Polanyi and Szabo[1] for the case of alkaline hydrolysis and by Datta, Day and Ingold[2] for the case of acid hydrolysis after Roberts and Urey[3] had shown that the same C—O bond is involved in the reverse process of esterification.

We have recently carried out a similar experiment on the alkaline hydrolysis of trimethyl phosphate, using aqueous sodium hydroxide prepared by acting with sodium on water enriched in the heavy oxygen isotope. The hydrolysis was carried out at 80–90° C. and proceeded until slightly more than one methyl group was removed. The resulting aqueous methyl alcohol was distilled off and purified by fractionation. The alcohol vapour was then passed over a red-hot platinum filament, whereby it was 'cracked' to give carbon monoxide and hydrogen. The mixture, plus excess hydrogen, was passed over a nickel catalyst and the carbon monoxide thereby reduced to water. This water thus contained the oxygen for the alcohol produced in the hydrolysis. Its density was measured, after purification, by the usual micro-pyknometer method[4].

The results are shown in the accompanying table, where $\Delta\rho$ (initial) is the excess density of the original water in parts per million and $\Delta\rho$ (final) is that of the water produced from the alcohol.

$\Delta\rho$ (initial)	$\Delta\rho$ (final)
180	0
180	+1
200	0

The results show quite clearly that during the hydrolysis the P—O bond of the ester is broken thus:



$$O{=}P\begin{matrix}\diagup OCH_3\\ -OCH_3\\ \diagdown OCH_3\end{matrix} + H\cdot OH \rightarrow O{=}P\begin{matrix}\diagup OCH_3\\ -OCH_3\\ \diagdown OH\end{matrix} + CH_3\cdot OH$$

The experimental error of the density measurement may be taken as ± 5 parts per million, so that at least 97 per cent of the hydrolysis must proceed indicated above.

This is a somewhat surprising result in view the fact that trimethyl phosphate is a fairly efficie methylating agent[5].

Density measurements of the residual water sho that, apart from the hydrolytic *replacement* of oxyge there is only a very slight *exchange* of oxygen betwee the water and the ester.

During the hydrolysis carried out as describe above, a considerable quantity of dimethyl ether produced. We are endeavouring to determine wheth or not this ether contains excess of ^{18}O, and also investigate the course of the hydrolysis in acid solution. We also hope to extend the work to oth inorganic esters.

Application of the Coincidence Method to Testin the Lifetime and Level Scheme of Radium C′

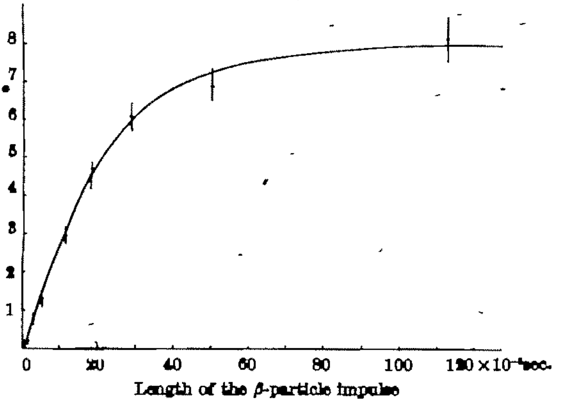
THE application of the coincidence method t investigations of nuclear processes may be extende in certain ways by using a variable resolving time the coincidence circuit and by measuring pseud coincidences, that is, counts arising from two impulse which are not simultaneous but separated by a ver short time. The number of 'coincidences' given b two particles, in which one follows the second in time determined by the radioactive constant λ, proportional to $1 - e^{-\lambda\tau}$, τ being the length of th impulse. The duration of the impulse is dependen upon the electrical constants of the circuit, and b changing the constants of one or both circuits it possible to obtain various determined lengths of th impulses. In order to measure λ, two sets of exper ments are made: (*a*) with the impulse τ_1 of the fir particle long and of different durations, and th impulse τ_2 of the second very short; (*b*) with th conditions reversed. The difference $a-b$ is equal $\frac{N_1N_2}{N}(e^{-\lambda\tau_2} - e^{-\lambda\tau_1})$ where N_1 and N_2 are the numbe of counts in each counter, N the number of di integrations. The method of lengthening the impulse only from one kind of particle allows one also decide the order in which the particles are emitted

In these experiments the method was applied the transformation

$$RaC \xrightarrow{\beta} RaC' \xrightarrow{\alpha} RaD.$$

Coincidences were observed between the various type of radiations, namely, $\alpha-\beta$, $\alpha-\gamma$, $\beta-\gamma$, and $\gamma-$ The β- and γ-radiations were measured in the usu way by means of Geiger-Müller tubes; the α-particle were counted separately by operating a Geiger-Mülle tube in the proportional region. The curve on th accompanying graph gives the number of re 'coincidences' ($a-b$) from radium C β-particles an radium C′ α-particles as a function of the length o the impulse from the β-particles. From this curv one obtains a value for the half-lifetime of radium C of $1{\cdot}40 \pm 0{\cdot}15 \times 10^{-4}$ sec.*

The investigation of the $\alpha-\gamma$ coincidences gives curve which is identical with the former, showin at no γ-radiation follows the emission of the -particle, and thus giving a direct proof that there o not exist any γ-rays of appreciable amount rising from the transition RaC′ → RaD. The easurements of the β−γ and γ−γ 'coincidences' ow no dependence on the length of the impulses, owing that none of the excited levels can have a fetime longer than 10^{-5} sec.



In order to check the level scheme of radium C′ of llis and Oppenheimer[1], sets of measurements were ade of the coincidences between β−γ and γ−γ due the radiations from radium C and C′. The β−γ incidences were measured as a function of the ab- rption of the β-particles. The result is that the ratio coincidences to the number of β-particles decreases pidly with the thickness of the absorber, but be- mes nearly constant for thicknesses of 1·3– mm. aluminium. The presence of coincidences at absorber thickness of 2 mm. aluminium shows at even the hardest β-group (upper limit 3·15 Mv.) connected with the γ-rays, in agreement with the heme of Ellis and Oppenheimer. This latter result in contradiction to the results of Bothe and Maier- eibnitz[2], who found no coincidences between the ard β-rays and the γ-rays, an observation very ifficult to reconcile with the level scheme.

Although my own results agree broadly with the vel scheme, a closer comparison shows certain iscrepancies; the decrease in coincidences with bsorber thickness is more rapid than expected, and e number of coincidences with the hard β-rays is o small. It ought to be mentioned that the com- arison is very dependent on the values adopted for e efficiencies of the γ-counter for rays of different ergy. Special experiments were made in order to etermine these values. The differences between the pected and experimental results are greater than e possible error in the determination of the ficiencies and must be explained in some other way.

The γ−γ coincidences were also measured as a nction of the thickness of lead between the source d one γ-counter. The shape of the experimental sorption curve of the relative number of coinci- nces is in fair agreement with the values expected om the level scheme.

Adsorption of Helium Gas on Active Charcoal between 4·2° and 1·78° K.

MEASUREMENTS have been made on the adsorption of helium gas on charcoal between 4·2° and 1·78° K. We determined the quantity adsorbed at various pressures and various temperatures. At the same time we also observed the adsorption velocity.

Above the λ-point, the adsorption seems to be normal. However, on passing the λ-point, the adsorption seems suddenly to be stopped (this could not be explained by the 'film' phenomena). Further, it seems to us that the adsorbed helium assumes a metastable state. The equilibrium pressure remained practically constant on lowering the temperature still further. However, at 1·97° K., the adsorption started suddenly again. It was also possible to get the adsorbed helium from this metastable state by a slight increase of temperature.

By increasing the temperature, starting from a temperature below the λ-point, it was again found that the adsorption becomes constant on passing the λ-point.

Briefly, it seems to us that the observed phenomena shows a certain analogy with 'critical' adsorption.

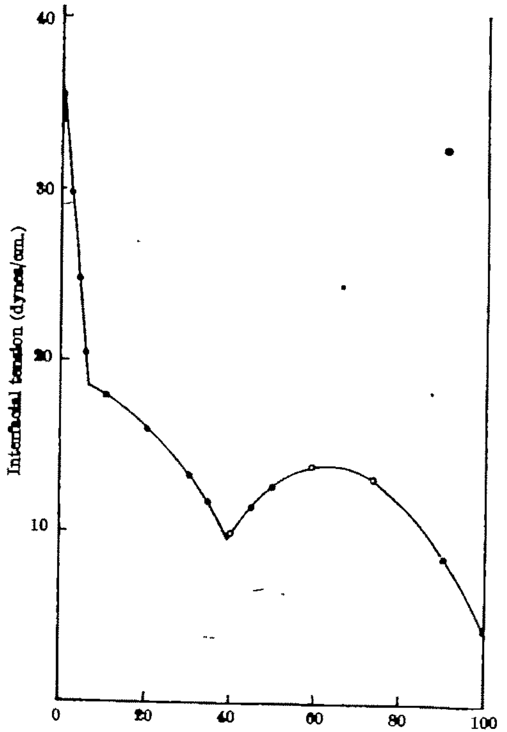
'Breaks' in Interfacial Tension Curves

WHEN a single solute is adsorbed from one phase to a water – oil interface, the interfacial tension usually falls in a regular manner with increasing adsorbate concentration, to a limiting value corre-



INFLUENCE OF BENZYL ALCOHOL ON BENZENE – WATER INTERFACIAL TENSION sponding to a close-packed monomolecular surface layer. In the very few cases[1] where exceptions have been found to this rule, the adsorbates have been soaps or similar hydrolysable molecules, and interattraction between the long-chain molecules and their products by hydrolysis has been given as explanation of the sharp breaks which occur in the interfacial tension – adsorbate concentration curves.

In order to test this, a study has been made of much simpler systems where no secondary reaction is possible. The accompanying graph represents the change in interfacial tension between water and benzene as molecules of benzyl alcohol accumulate at the interface, and was obtained by measuring[2] the tension between a water phase saturated with benzyl alcohol, and a benzene phase containing varying amounts of the alcohol. The curve shows two very well-defined breaks, indicating that such breaks must be due to a much simpler cause than has hitherto been believed; it is suggested that they occur whenever an amphipathic adsorbate is soluble in both phases, and that the *two* breaks which normally occur represent the beginning and the end of interpenetration of two identical adsorbed films. It is significant that no break is obtained in the curve for benzyl chloride, which is soluble only in the benzene phase.

On the Theory of Dielectric Polarization in Liquids

ONSAGER[1] has developed a theory of the dielectric polarization in liquids, in many respects different from the current theory of Lorentz-Debye. We propose to show that the method of calculating the dipole energy, used by Onsager in his theory, does not correspond exactly to the assumptions of this theory. Onsager calculates the momentum of forces rotating the molecule in such a manner as if the rotation of the resulting moment (being the vectorial sum of both the permanent and induced moment) were decisive for the rotation of the molecule. In fact, however, only the axis of the permanent moment, and not that of the induced moment is rigidly bound to the isotropic molecule. This fact causes the real expression for the energy of the molecule to differ from the formula presented by Onsager. We obtain therefore instead of Onsager's formula:

$$\frac{4\pi N\mu^2}{9kT} = \frac{(\varepsilon-n^2)\,(2\varepsilon+n^2)}{\varepsilon(n^2+2)^2} = \rho(\varepsilon, n), \quad . \; . \; (1)$$

the following expression:

$$\frac{4\pi N\mu^2}{9kT} = \rho(\varepsilon, n) \cdot \frac{2\varepsilon+n^2}{2\varepsilon+1} \cdot \frac{3}{n^2+2}, \quad . \; . \; . \; (2)$$

where μ denotes the permanent moment of an isolated molecule (that is, measured in the vapour state), ε is the dielectric constant of the liquid, n is its refractive index (for $\lambda = \infty$) and N is the number of molecules per ccm.

Böttcher[2] has proved on ample experimental data that formula (1), when applied to numerous liquids, gives for μ values in excellent agreement with those determined from measurements of the dielectric constant of vapours. If we apply, on the other hand, to the same liquids the corrected formula (2), we obtain lower values, generally by about 15 per cen The deviations therefore between Onsager's theor and experiment become rather considerable. F example, for nitrobenzene, in which $\mu = 4{\cdot}2$ (deter mined in the vapour), formula (1) gives $\mu = 4{\cdot}$ while formula (2) gives $\mu = 3{\cdot}6$.

Onsager deduces also an expression for the rati $\mu_{app.}/\mu$, where $\mu_{app.}$ denotes the dipole moment dete mined by Debye's method applied to solutions i non-polar solvents. We have shown that the valu of this last expression turns out to be greater than for such solutions as nitrobenzene-hexane, nitr benzene-benzene and others. It is, however, generall known that numerous experiments yield $\mu_{app.}/\mu <$

The question will be discussed more fully in a pape to be published shortly in *Bull. Ac. Pol.*

Avoidance of Crystal Formation during Embeddin of Plant Material in Paraffin Wax

THE formation of wax crystals in paraffin block containing material for microtoming is a commo source of annoyance. As a result of various trial I have found that the following simple metho eliminates the trouble, at least in so far as the variou types of wax used in this department are concerne

Float 'boat' containing melted wax and materi suitably spaced in a 500 c.c. beaker containing wate the temperature of which is within a few degrees zero and in which ice is floating. As soon as possib submerge block and remove it from 'boat'. Kee block submerged until hard, and repeat process unt all material has been embedded. Then transfer th beaker containing the paraffin blocks to a refrigerat at a temperature about 5° or 6° C. and leave the for one or two days. Then remove beaker fro refrigerator, and allow the water and wax therei gradually to assume the temperature of the atm sphere. The paraffin block is now ready for immediat or future use.

Insects in Aircraft

DR. WHITFIELD's recent communication on th problem[1] rightly emphasizes its importance. But might be gathered from his letter that it is a ne problem—one which has hitherto received litt attention or one for which no adequate preventiv measures have been devised.

Such assumptions would be wrong. The proble has exercised the minds of tropical sanitarians a least since the time of Manson, and the danger one which has been reiterated on many occasion by the Ross Institute and other authorities. Activ measures have been taken and are being taken b aircraft companies and by the sanitary authoriti various African airports, notably Cairo, Khartoum nd Durban, to minimize or abolish noxious insects om aircraft.

The work of Dr. Park Ross of Durban, Mr. C. B. ymes of Kenya Colony, the Entomological Staff of e Government of India and by ourselves, as well the valuable work of Mr. Whitfield himself at hartoum, has served to throw considerable light n this problem and the measures taken to meet it. Ve[2] have found that there are at least two efficient queous base pyrethrum insecticides on the market hich, applied in the dilutions we suggest, will ensure e death of mosquitoes and other flying insects in ircraft within a few minutes of application.

Preparations of pyrethrum are being used all over e world by aircraft companies and ground sanitary uthorities, and we may safely say that science has rovided the means of abolishing the danger of insect ansmission by aircraft, and it only remains for nternational authorities to insist on these measures eing carried out.

The authority responsible for these regulations is the International Sanitary Convention for Aerial Navigation, but this body has unfortunately laid down no precise rules on the subject. The responsibility for doing this and the manner of doing it is at present left to the decision of each authority concerned, with the result that the methods used in different countries vary considerably in their efficiency.

It is hoped that Mr. Whitfield's letter will impress all concerned with the necessity of concerted action to meet this danger, in place of the inco-ordination of effort which at present exists.

Points from Foregoing Letters

RAPID application of pressure to beech leaves which ave coloured vacuoles expresses sap of low osmotic ressure (about one third of the plasmolytic value) ontaining 80 per cent of the vacuolar pigment. . A. Bennet-Clark and Dorothy Bexon support the ontention of Phillis and Mason that this treatment xpresses vacuolar sap rather than water which is ltered from the solutes.

W. Dulière and O. Loewi have found that acetylcholine, when applied after eserine, liberates ionic otassium in the isolated nervous system of the frog.

L. Laszt finds the inhibiting effect of iodoacetate n glucose absorption from the intestine of rats is sup-ressed by sodium chloride in a similar way as sodium lts counteract the symptoms of adrenalectomy.

J. P. McGowan shows that an important phase in e histogenesis of red blood cells in pernicious and ome other anæmias would appear to be the multilication of the hæmocytoblasts by amitotic division nd the subsequent ripening of these into erythroytes. When nicotinic acid is administered, it is uggested that this forms with the pentose-nucleotides resent in the cytoplasm of the hæmocytoblasts—the oenzyme system. The latter then plays an important art in the development and mitotic division of the rythroblasts which are now the cells which ripen to rythrocytes.

4 : 4′-dihydroxystilbene and benzoic acid have been olated by S. W. Stroud as metabolic products from he urine of rabbits injected with stilbene.

H. Liche and K. Wodzicki describe the vaginal mears obtained during various phases of the œstrous ycle of cats. The similarity between smears for cats nd lionesses is pointed out. In both species, the mears may serve for diagnosis of the phase of the estrous cycle.

By thermal decomposition of cholesteryl oleate, 3,5-cholestadiene was obtained by H. Veldstra. n feeding experiments by Waterman with mice this ubstance caused papillomas of the stomach, one of hich showed infiltrating properties. As cholesteryl thers normally occur in fats, the formation of arcinogenic substances by heating of fats has to be onsidered as possible.

Further analyses of solasonine and solasodine are in agreement with molecular formulæ, $C_{44}H_{73}O_{16}N$ and $C_{27}H_{43}O_{2}N$, for these bases, and from chemical evidence a constitutional formula for solasodine is proposed by L. H. Briggs. A comparison of its chemical properties with those of solanidine indicates that solasodine is possibly a hydroxy derivative of solanidine.

By using water containing excess of heavy oxygen isotope J. B. M. Herbert and E. Blumenthal show that the mechanism of hydrolysis of trimethyl phosphate in alkaline solution is the same as that for the hydrolysis of the simple organic esters. That is, that the rupture occurs at the P–O bond of the ester.

By the use of a coincidence apparatus with a variable resolving time, J. Rotblat has found the half value period of radium C′ to be $1{\cdot}40 \times 10^{-4}$ sec. He has also shown that no γ-radiation is emitted in the transition radium C′ → radium D. Coincidence observations on the radiations emitted in the process radium C → radium C′ → radium D have also been made, from which deductions concerning the level scheme of radium C′ are drawn. The results confirm in general the accepted level scheme, but certain discrepancies remain to be examined.

C. C. Addison finds that the breaks in interfacial tension curves, usually associated with complex systems, are found to occur in the simple benzene–benzyl alcohol–water system; he believes them to be due to penetration of two identical adsorbed layers.

K. Zakrzewski and A. Piekara criticize Onsager's theory of dielectric polarization in liquids, and give a modified expression for Onsager's formula which corresponds more strictly to the assumptions of the theory. This theory, however, yields values deviating considerably from the experimental data.

P. Brough describes a simple method whereby crystal formation, commonly experienced during embedding of plant material in paraffin wax, may be avoided. The essentials of the process are rapid cooling of wax during embedding, the immediate transfer of the blocks to a refrigerator and the gradual bringing of the temperature of the wax to that of the laboratory.

RESEARCH ITEMS

Maya Mounds of British Honduras

THE late T. W. Gann, with Mary Gann, in the course of two seasons spent in the Corozal District of British Honduras, between the valleys of the Rio Hondo and the Rio Nuevo examined by excavation a number of mounds belonging to the ancient Maya civilization. These centred around a group of large banks and mounds known to the Indians as Nohmul, or Great Mound, so called because one of the pyramidal structures is the loftiest in the district, reaching a height of 95 ft. In a report on the excavations (Smithsonian Institution: *Anthropological Papers Bull.*, 123; 1939), Dr. Gann points out the probable influence of a liberal water supply in determining the choice of this site for settlement. In all, 28 mounds were examined, these falling into six distinct groups. (1) Burial mounds unassociated with either cists or stucco floors, numbering ten in all, probably the graves of poor people, grave furniture being scanty and poor. (2) Sepulchral mounds with the corpse buried above or below the former floor of a house. Of these there were four; and they probably belonged to householders of sufficient importance to have their houses wrecked and converted into burial mounds. (3) Sepulchral mounds containing specially constructed burial cists. These, including the great mound of Nohmul itself, number eight. They vary in height from 9 to 95 ft., and contain all the finest artefacts of shell, stone, pottery, etc. In some the cists were beneath the floors of houses, in others the mounds were constructed specially to cover them. (4) Mounds constructed over the ruins of stone buildings and not used for sepulchral purposes—five in number, all flat-topped, and of very solid masonry. (5) Mounds built over the former floors of wood or adobe buildings, not containing burials. Of these there were two, each appearing to have been low stucco-covered substructures of houses of perishable materials. (6) Mounds containing only fragments of crude clay censers. Two were examined.

Ontogeny and Phylogeny of the Human Nose

THAT very prominent feature of the human face, the outer nose, its various types and their methods of growth, have been investigated by C. B. Benedict (*Proc. Amer. Philos. Soc.*, Jan. 1939). The anatomical elements concerned in the formation of the outer nose are considered and their histories in the foetus outlined. Five absolute measurements and eight ratios are employed for the purpose of statistical definition. A large series of measurements on persons from three to twenty years of age and of different races were taken. Nasal height increases *pari passu* with stature; but becomes greater in boys than in girls. This sexual difference, which is widespread, is due in large measure to the greater body size in boys, on the average; but also to the earlier differentiation of the nose in the female which is related to the earlier assumption of maturity. The wide diversity of the shape of the nose in various races suggests that a number of different genes are involved in its development. Comparison with lower forms suggests that the ontogenetic succession follows the phylogenetic steps.

Determination of Histamine in Biological Extracts

M. ROCHA E SILVA, of the Instituto Biologic S. Paulo, Brasil, has introduced a slight alteration Code's method for estimating histamine, whic permits a big reduction in the final volume of th extract (*Arqu. Inst. Biol.*, 9, 145; 1938). Code method is a modification of that of Barsoum a Gaddum. In this last technique, after removing th proteins by trichloracetic acid, and the acid by ethe the filtrate is boiled with hydrochloric acid for minutes and then dried *in vacuo*. The dry resid is extracted with hot alcohol saturated with sodiu chloride. Code has shown that the most serious lo of histamine occurred in the extraction of the drie residue by alcohol. Aqueous extraction in Code method gave higher and more consistent recoverie but the removal of an excess of salts that was possibl by Barsoum and Gaddum's method is not possibl by Code's method. It is true that it was shown b Code that the salt content of extracts of the bloo constituents does not interfere with the reaction the guinea pig ileum to histamine; but in certai circumstances it may be very important to effect big reduction in the final volume in order to attai more accurate results. The following technique ha been devised: (1, 2) The filtrate, after precipitatio with trichloracetic acid, is boiled with one tenth its volume of concentrated hydrochloric aci (3) This boiling is carried out until crystallizatio of the salts begins. The water is also carefull evaporated, avoiding any deposition of solid cake on the wall (complete dryness must also be avoided (4) A few c.c. of 96 per cent alcohol saturated wit sodium chloride is added. Filtration allows a complete removal of the precipitated salts. The filter washed out repeatedly with the same 96 per cen alcohol saturated with sodium chloride. (5) Th filtrate is dried *in vacuo*, the hydrochloric acid removed by repeated additions of absolute ethyl alcoho and (6) the residue dissolved in a small volume saline. The removal of the excess of salts permits big reduction in the final volume of the extract without interference with the guinea pig gut reactio for histamine. This method is being used for determining the histamine content in fluids (blood plasma where the usual content is very low.

Sex Determination in Melandrium

H. E. Warmke and A. F. Blakeslee (*Science*, 8 391–392; 1939) have studied the sex determinatio in polyploid forms of Melandrium produced by colchicine treatment. Plants of the chromosome constitution $3A + XXY$ and $4A + XXXY$ are fertil males whereas $4A + 3X$ is a female. This indicate that the Y-chromosome is active in sex determination, contrary to the situation in Drosophila. hermaphrodite results from the constitution $4A$ + $4X + Y$. 37·5 per cent of the meiotic association in an $XXYY$ complex consist of $X - X$ and $Y - Y$ bivalents, and the remainder are chiefly association of 4 chromosomes. It is pointed out that a polyploid sex mechanism of $XXXX$, $XXXY$ is comparable in efficiency and survival value with that i the diploid.

fteen Years' Research on Datura

A. F. Blakeslee and A. G. Avery ("Co-operation Research", Carnegie Institute, 501, 315–351; 38) have summarized the data on 60,000 trisomic ants in *Datura stramonium*. The viability of the imary and secondary trisomics differs widely, nging from 32·7 per cent for $2n + 23\cdot24$ to 3 per nt for $2n + 19\cdot20$. The proportions of primaries rown by the related secondary trisomics also varies, d this indicates that disjunction is not at random. ore unrelated primaries are given by primaries than normal types, indicating that general non-sjunction is more common in $2n + 1$ types than diploids. Double trisomics $2n + 1 + 1$, however, ow a decreased production of unrelated primaries. tes of non-disjunction are different in different romosomes, and these are not correlated with the e of chromosome.

lorophyll Deficiencies in Red Clover

R. D. Williams (*J. Genet.*, 37, 440–458 and 459–1) has identified genetically eight genes for albino edlings and seven for yellow, chlorophyll-deficient hal seedlings in red clover. In addition, ten other ino and nine other yellow chlorophyll-deficient pes were found. Linkage between some of these pes and morphological characters is demonstrated. and *y*[illegible] act both as embryonic and seedling lethals, ile the chlorophyll production of *y*[illegible]*y*[illegible] varies greatly th the environment.

bridization in Yeast

O. Winge and O. Laustsen (*C.R. Trav. Lab. rlsberg*, 22, 337–352; 1939), continuing their work yeasts, have made several hybrids between various pes of yeast belonging to the species *Saccharomyces licus*, *S. cerevisiae*, *S. Mandshuricus*, *S. validus*, *gosaccharomyces Priorianus*. Two haploid spores placed in a drop of a culture solution and allowed form a diploid zygote. It was found that five brids showed low germination (0·13 per cent) of zygote, while six gave a germination of between and 94 per cent. The relationships of the parents y therefore be determined. It is found that these ationships correspond to the properties shown by types in biochemical fermentation.

male Reproductive Organs of the Toad

The female reproductive organs of the toad *Bufo narum*, their cyclic changes, and the effect thereon the hypophysis, have been studied by Inés Lopez lombo de Allende (Inst. Physiol. Cordoba, Argen- a). The cycle of changes falls into three parts: period of rest from the end of summer to the lowing spring; a period of activity from the last rt of spring to early summer, and a period from er oviposition until the end of summer. The anterior uitary factor induces ovolution and secretion of glands of the Müllerian ducts. The influence of hypophysis is complex, but on the full-grown ary it causes the larger ovules to be freed and charged, and this effect is produced in the isolated ary even if this be placed in the abdomen of a le. Mammalian hypophyseal implants have no luence. Homo-implants of the hypophysis induce ndular activity in the Müllerian ducts, but repeated plants result in degeneration. Hypophysectomy induces involutive changes in the oviducts. Sexual hormones of mammals produce no effect in this toad, which is somewhat remarkable in view of their striking effects in *Xenopus laevis*.

Australian 'Sooty Moulds'

Miss Eileen E. Fisher has recently published an important study of the 'sooty moulds' of Australia (*Ann. Bot.*, 3, New Series, No. 10, 399; April 1939). After a critical analysis of previous investigations and a discussion of the taxonomy of these moulds, a classification is proposed by which they are grouped according to the microscopic appearance of their growth. With the exception of Trichothyriaceæ, six families are discussed. Capnodiaceæ and Chaetothyriaceæ have therefore been amended. The geographical distribution of epiphytic 'sooty moulds' is considered in relation to temperature and humidity requirements, and from this it is suggested that the rarity of species of Capnodiaceæ in cool temperate climates may be due to the deciduous vegetation. A bibliography, four text-figures and one plate are appended.

Parasitism of the Pitch-Crust Fungus

The pitch-crust fungus, *Ustulina vulgaris*, causes a disease of the heart-rot type in trees of temperate climates. W. H. Wilkins has made several studies of the means of infection, and in the latest paper (*Trans. Brit. Mycol. Soc.*, 23, Pt. 1, 65–85; May 1939) he concludes that conidia of the fungus are the most probable means of infection in Nature. They are produced in abundance, are easily dispersed, they germinate readily at the temperature of normal climate, and their germ tubes penetrate most kinds of timber quite readily. The author, moreover, came to the conclusion in an earlier paper that ascospores could not infect timber under natural conditions. The conidia are about 7·3μ × 3μ; they germinate readily between 5° C. and 30° C., and between relative acidities of pH 2 and pH 9. Oak wood is not readily penetrated, and the fungus seems to enter green wood more easily than seasoned timber. The paper contains other details of spore longevity and germination, and has adequately paved the way for further studies upon control of this particular heart-rot.

White Mould Disease of the Daffodil

The fungus *Ramularia Vallisumbrosæ* attacks the leaves of all varieties of Narcissi, and often assumes epidemic proportions in districts where daffodils are grown for flower production. Taxonomic characters and the life-history of the parasite have been studied by P. H. Gregory (*Trans. Brit. Mycol. Soc.*, 23, No. 1, 24–54, May 1939), who also has a further investigation in progress upon control of the malady. Sunken grey lesions appear on the leaves, and later produce conidia, which can re-infect other foliage. The fungus makes small sclerotia when the dormant period deprives it of the green parts of its host. Sclerotia have not been found in the bulb, and the organism appears to depend upon the production of conidia from sclerotia in spring, for re-infection from year to year. This fact should be important in control of the disease, for dead infected leaves could be removed. Isolation and re-inoculation experiments from conidia upon the leaves and from sclerotia have confirmed the essential features of the life-history. *R. Vallisumbrosæ* was first described by Cavara in 1899; but *Cercosporella Narcissi*, described by Boudier two years later, appears to be synonymous. Spore characters of the fungus warrant its inclusion in either of the genera mentioned, but the retention of the earlier name is proposed in the present paper.

Long-Wave Phase of Earthquakes

CONTINUING his work on this phase of earthquakes, Stoneley (*Mon. Not. Roy. Astro. Soc.*, Geophys. Supp., 4, No. 7, 562; June 1939) has made an analysis of the times of transit of the phase as given in the International Seismological Summary for fifteen well-observed earthquakes, and has shown that this gives a frequency distribution which is strongly double-humped. The maxima correspond to travel-rates of approximately 0·420 and 0·467 minutes per degree, and these refer to the onsets of the Love-wave and Rayleigh-wave phases which are usually denoted by *LQ* and *LR* respectively. Significant differences in the relative frequency of *LQ* and *LR* in different shocks are shown to occur for earthquakes in the same epicentral region, and these seem to indicate, according to the author, differences in the type of dislocation at the focus. It is pointed out that the ratio of the velocities is 0·90, which is in fair agreement with the predicted ratio of 0·92.

Scattering of Protons by Protons

R. G. Herb, D. W. Kerst, D. B. Parkinson and G. J. Plain (*Phys. Rev.*, 55, 998; 1939) have investigated very carefully the scattering of protons in hydrogen for angles between 15° and 45° and proton energies between 0·86 mev. and 2·4 mev. Full experimental details are given in the paper. Rather elaborate work is necessary to determine the absolute scattering cross-sections for comparison with Mott's theoretical calculations. The scattering at 15° agrees well with this theory for all energies, but at larger angles and high energies the observed scattering is much larger than the theoretical. It is 43 times as big as the theory predicts at 45° and 2·4 mev. energy. G. Breit, H. M. Thaxton and L. Eisenbud (*Phys. Rev.*, 55, 1018; 1939) discuss the theoretical significance of these and other recent experiments on proton proton scattering. The calculation of experimental corrections is discussed at length, and the results are then analysed in terms of the nuclear forces. No evidence was found for a nuclear *p* wave, and a good fit was obtained with an *s* wave and an interaction potential of 'square well' shape with a radius $= 1 \times e^2/mc^2$: $2{\cdot}8\ 10^{-13}$ cm. A potential curve of 'Gaussian' form could also be made to explain the results with appropriate choice of parameters.

Spectrum of Comet 1939*d*

A COMMUNICATION has been received from F. Hinderer, Babelsberg, through *Zirkular der Astronomischen Nachrichten*, which describes the spectrum of this comet. Using the Babelsberg reflecting prismatic camera with a dispersion 240 A./mm. at the $H\gamma$ line on April $18^{d}\ 20^{h}\ 43^{m}$ U.T. and also at $21^{h}\ 04^{m}$ U.T. an extraordinarily fine detail of structure was revealed. In the head there was a continuous spectrum with very strong emission
bands. These were clearly and sharply differentiate
and the edges of the single bands were visible.]
the violet end of the spectrum the emission hea
4200, 4050 and especially 3885 were the stronge
members of the cyanogen bands. In the first to t
fourth carbon bands (C_2), approximate wave-lengt
5635, 5540, 5585, 5129–5165, and 4685–4737, tl
strong heads of these were largely responsible for t
yellow colour in the integrated light of the come
In addition, there was an emission at about 4300 a
also an emission on the red side of the first carb
band. As the direction of dispersion and that of t
tail are in close coincidence, little can be said abo
the spectrum of the latter. Certainly, in accordan
with the usual experience in cometary spectra, t
bands mentioned above in the spectrum of the he
are absent in that of the tail, although the fir
emission bands between 5635 and the red lim
of sensitivity of the plate is found again in the ta

Rate of Rotation of the Earth

IN a paper entitled "The Rotation of the Eart
and the Secular Accelerations of the Sun, Moon a
Planets" (*Mon. Not. Roy. Astro. Soc.*, 99, 7; M
1939) H. Spencer Jones derives important results f
the accurate prediction of eclipses, if the tabul
error of the moon's longitude is known. It has be
established that the fluctuations in the longitud
of the sun, Mercury and Venus run closely parall
to those of the moon's longitude, for which reason
these fluctuations have been attributed to a comm
cause—a variation of the adopted unit of time pr
vided by the rotation of the earth. The variations
the rotation of the earth have been attributed to tid
friction, and also to changes in the moment
inertia of the earth, due to some redistribution
matter in its interior. If changes in the moment
inertia of the earth take place, the effects on t
longitudes of the sun, moon and planets are pr
portional to the respective mean motions of the
bodies. In the case of tidal friction, a change in t
angular momentum of the earth occurs and this mu
be compensated by a corresponding change in t
angular momentum of the moon's orbital rotatio
The effect on the longitude of the moon is too sm
to be predicted by theory. Observational data co
firm the view previously mentioned that the secul
accelerations are proportional to the mean motio
but the results for Venus do not cover a long enou
period to determine the secular acceleration of t
planet with great accuracy. It is interesting to noti
that the effects of tidal friction are less at prese
than the average effects over the past 2,000 yea
In addition, de Sitter's suggestion that large a
sudden fluctuations in tidal friction take place h
not been confirmed. The results obtained can
summarized as follows: Let ΔL, Δl_1, Δl_2 be t
corrections required to the mean longitudes of t
sun, Mercury and Venus, respectively, as given
Newcomb's Tables, and let T be expressed
centuries measured from 1900·0. A quantity
defined as the *fluctuation* in the moon's longitude,
obtained from the moon's observed longitude,
which certain corrections for Brown's Tables a
applied. Then:

$$\begin{aligned}\Delta L &= 1{\cdot}00'' + 2{\cdot}97''\,T + 1{\cdot}23''\,T^2 + 0{\cdot}0747\,\beta\\ \Delta l_1 &= 4{\cdot}96'' + 13{\cdot}08''\,T + 5{\cdot}10''\,T^2 + 0{\cdot}310\,\beta\\ \Delta l_2 &= 2{\cdot}26'' + 5{\cdot}39''\,T + 2{\cdot}00''\,T^2 + 0{\cdot}112\,\beta.\end{aligned}$$

KENYA'S PASTORAL NEEDS

1929, an agricultural commission under Sir Daniel Hall reported on the grave condition to ich certain native reserves in Kenya had been uced as a consequence of overgrazing and soil sion, and recommended an immediate reduction livestock and an increase in agriculture as means ountering a serious and growing menace to the stence of the country. In 1931, Sir Frank Stock- e reported that an increase in agriculture and sequent reduction of area available for grazing re accentuating the dangers of erosion. In 1933, Kenya Land Commission recommended an ension of the cropped area, using dry-farming thods, in order to increase production in densely pulated reserves. In 1936, Sir Alan Pim's report Kenya directed attention to the danger of extend- ; the cultivated area without suitable precautions ng taken to maintain fertility, and to the absence any definite policy with regard to soil erosion. 1937, both Sir Frank Stockdale and the recently pointed soil conservation officer (Mr. C. Maher) ressed the view that the overworked land needed omplete and prolonged rest without which much it was irretrievably doomed. They further recom- nded the development and intensification of agri- ture to compensate for loss of production from sted' land.

This summary of the recommendations of some of consulting 'physicians' who have attended Kenya the last ten years of its decline is given (in more tail) in Dr. Pole-Evans's account of a visit to the lony last year.* It will be noticed that all the er physicians recognized that the worst affected rts needed rest, but proposed to maintain pro- ctive capacity by throwing an additional burden to other parts, that is, by extending agriculture. at the productive capacity of the native reserves st be maintained at a certain minimum in the immediate interests of the inhabitants is the burden of these physicians' arguments. Dr. Pole-Evans is more forthright in his recommendations. He is a South African ecologist who lacks the bedside manner of the official reporter or commissioner. He considers that the situation is so grave that the complete rest which should have been given years ago is now imperative and must be given regardless of economic and political obstacles, if a greater future disaster is to be avoided. The remedy he proposes is simple on paper; it has been used time and again in history to rest exhausted land while keeping it under human control, and it has rarely failed. It consists in restoring the natural grass cover and utilizing animals in suitable numbers to keep the grass in good condition. It means a general reversion to less productive pastoral farming with greatly reduced stock in densely populated native reserves. Dr. Pole-Evans admits the value of supplementary measures of soil conservation—afforestation, terracing, strip-cropping, etc.—but they are practically useless unless the foundations of native society are grounded in pastures. The population can only support itself on a predominantly pastoral basis if administrative intelligence and action are concentrated on the problem of growing luxuriant grass on exhausted land in a semi-arid climate. The solution of that problem will demand all the resources of science backed by wise and far-sighted administration, and Dr. Pole-Evans's report is a plea that the necessary help and encouragement of the right kind be given before it is too late.

The report is depressing in the extreme, but it carries deadly conviction. One wishes that it could be read and its implications understood by every member of parliament. We might then get the beginnings of a Colonial policy which takes account of the harsh—the very harsh—realities of Nature that will determine policy in the end.

G. V. J.

Report on a visit to Kenya. By Dr. I. B. Pole-Evans. Pp. 36+18 tes. (Nairobi: Government Printer, 1939.) 2s. 6d.

THE ROYAL SOCIETY OF CANADA

Annual Meeting

HE annual meeting of the Royal Society of Canada was held at the University of Montreal the new Botanical Building during May 22–24. A ge attendance of fellows from all parts of Canada d an opportunity of seeing this splendid new velopment of a botanical garden in Montreal with laboratories, greenhouses and large park still in progress of completion as a works project financed civic and Government authorities and under the ection of Frère Marie-Victorin of the University Montreal.

The presidential address was delivered by Dr. ctor Morin, who spoke on "La Chanson Française travers les siècles", with interpretations of songs the "Quatuor des Alouettes". This address was ceded by the introduction of new fellows and by presentation of medals awarded by the Society. The Flavelle Medal was awarded posthumously to the late Prof. J. Playfair McMurrich in recognition of his distinguished work in anatomy. Dr. Wilfred Bovey received the Lorne Pierce Medal, and the Tyrrell Medal was presented to Dr. E. Z. Massicotte. A unique social feature of the meeting was the Operetta-dinner held in the ballroom of the Mount Royal Hotel, at which the fellows and their wives were the guests of the City of Montreal. This fanciful dinner-play was written by the president of the Society, Dr. Morin, as a reconstitution of the feasts given by the 'seigneurs' of olden times. Parodical rhymes on gastronomical subjects adapted to the music of well-known operas of the French repertory were sung by artists in cook's and maid's costumes, as the several dishes of the dinner were served.

At the concluding general meeting, Dr. H. M. Tory was elected the new president of the Society.

Section III (Chemical, Mathematical and Physical Sciences) was held under the presidency of Prof. S. Beatty, who delivered the presidential address on "Generalisation as a Principle of Mathematics". Three new members were elected to this section, Prof. H. N. Brocklesby, Prof. M. F. Crawford and Prof. G. Herzberg. In all, 120 papers were presented and the section split into the three subdivisions to facilitate the giving of the papers during the time of the meeting.

Prof. E. F. Burton spoke on a number of papers contributed by his co-workers, among which special mention should be made of the recent results obtained by Johns, Wilhelm and Grayson Smith on the flow and viscosity of liquid helium, in which it was proved, by using glass capillaries ranging from 0·025 cm. to 0·0036 cm. in diameter and with lengths varying from 2 cm. to 26 cm., that normal laminar flow was obtained for He I with a viscosity of the order of 10^{-5} c.g.s. units, while for He II, the flow could be expressed as the sum of a laminar flow plus an additional pressure-independent flow. The laminar portion obeyed Poiseuille's law and gave a viscosity of the order of 10^{-5} c.g.s. units. The new electron microscope constructed by A. Prebus and J. Hillier and photographs obtained with it indicating high resolving power were described by Dr. Burton. Among the papers presented by Prof. J. A. Gray, one in collaboration with J. S. Marshall and A. G. Wood contained results on the scattering of β-rays using metallic foils, which were in contradiction to those obtained by other observers using expansion chamber methods. Dr. D. C. Rose described an electromagnetic pick-up device used with a cathode ray oscillograph for investigating vibrations in aeroplanes during flight. A new method of observing the Raman effect in small amounts of liquid with short exposure times was presented by Prof. M. F. Crawford and H. L. Walsh.

A description of the methods now being used to determine the upper earth structure from data obtained by registering the seismic waves from rock bursts occurring in mines was given by Dr. E. A. Hodgson. Other papers on field results of geophysical investigations were given by Dr. A. A. Brant, Prof. L. Gilchrist and Prof. D. A. Keys. The results of an analysis of meteorological data by A. Thomson showed that the average winter temperature was 4° F. warmer in Manitoba and Saskatchewan for the period 1919–1938 than for the period 1884–1903, which was explained by the increase in the temperature of the air-masses moving in from the Arctic circle.

Among the fifteen papers presented by Prof. O. Maass and his associates, particular interest was taken in those dealing with the measurements of viscosity, opalescence, specific heat, density and solubility relations of various liquids and vapours in the critical temperature region. The influence of intense mechanical stirring on the temperature at which the disappearance of the meniscus takes place shows that a wide range of over-all density gives identical critical temperatures. Prof. E. W. Steacie presented eight papers dealing with various aspects of photosensitized decomposition. Prof. R. H. Clark and his collaborators contributed fourteen papers, among which special mention may be made of the results obtained on activators of zymase. The plant hormones activate live yeast but have little accelerating effect on zymin. Another paper interest was on the mechanism of the flotation galena in the presence of xanthate which is appl in the mining industry in Canada. Prof. H. Hibb spoke on the results obtained in his laborato carried out with various collaborators, on lignin a other wood products.

In the mathematical and astronomical secti M. S. McPhail and Prof. R. L. Jeffery spoke Stieltjes integrals with applications to fractio integrals. The profiles of hydrogen lines in spectrum of *H.D.* 190073 by C. S. Beals and investigation into the hydrogen line contours in spectra of solar stars by K. O. Wright were given Dr. W. E. Harper. Dr. A. V. Douglas, D. C. W and D. E. Guignard described an investigat on the profiles of hydrogen lines in two class stars.

Prof. J. A. Gray was elected president of section and Prof. J. K. Robertson secretary.

In Section IV (Geological Sciences) the president address by Dr. M. E. Wilson outlined the devel ment of ideas about the Canadian Precambrian discussed certain Precambrian problems. Eighte papers were presented. Two papers dealt wi Sudbury, one by Dr. H. C. Cooke, in which so new ideas about the general geology of the distr were given, and the other by Dr. A. B. Yates c cerned with the ore deposition. Dr. H. C. Gunni and J. W. Ambrose outlined the results of five ye detailed investigation of the so-called Timiskamin Keewatin contact in Rouyn-Harricanaw Ar Quebec. The whole succession of volcanic a sedimentary rocks is apparently conformable a the investigations show the need for compl revision of our conceptions of Archean strat graphy and structure in this part of the Canadi shield.

The palæontological papers included descriptio of a Helderber fauna from the eastern townships Quebec by D. T. H. Clark, and some species of Ne Triassic ammonites by D. L. H. McLearn. Dr. J. Wilson presented an interesting paper on the Esk north-east of Great Slave Lake, N.W.T. T information was gained chiefly from the study aerial photographs.

Dr. H. W. Fairbairn presented a paper on t fracture hypothesis of quartz orientation in tect nites. Dr. M. B. Baker discussed the floor of t Palæozoic rocks in Canada.

The presidential address of Section V (Biologi Sciences) was delivered by Dr. J. M. Swaine Ottawa on "Scientific Research as the Key Progress in Agriculture".

The programme comprised seventy-two papers, which nineteen came before the medical subsectio and twenty-nine were botanical.

Dr. N. H. Grace reported upon the relative physi logical activity of the members of a series of naphth acids when applied to plant cuttings, showing th those with an even number of carbon atoms in t side chain are the more active. Drs. E. Gord Young and R. W. Begg found certain small prop tions of copper, calcium, magnesium, and iron to required in bacterial culture media. Factors affecti stomatal movement in the dark were described J. H. Whyte. That increased permeability of t host accompanies increased susceptibility to pa sites and diseases in plants was shown by F. Thatcher. The importance of boron for normal c division, enlargement, and maturation in plants w cribed by J. G. Coulson and R. O. Lachance, le studies related to hardiness of plants were orted, by Messrs. J. Levitt and D. Siminovitch. B. Thomson discussed the structure of the pollen e of Austrotaxus and its phylogenetic significance, wing it to be a highly specialized derivative of usual conifer type, and C. N. Haldenby described distribution and origin of horizontal resin canals Coniferæ. A series of papers by Frère Marie-torin was devoted to various taxonomic and ributional studies of the plants of Quebec and of e, interesting contributions to the problem of floras being made, particularly in papers by . Rousseear and Gauthier.

n the field of genetics, a definite relationship ween sterility and chromosome segregation with nslocations was demonstrated in wheat crossed by P. Thompson, and the actual causes of failure of d-setting in certain intergeneric cereal crosses e described in another paper by the same investi-or. F. H. Peto gave an account of the production fertile amphibolypoid plants from sterile hybrids Triticum species, and A. Glaucum, by temperature l colchicine treatments, with cytological studies of processes involved. Certain chromosome muta-s in oats were shown by H. G. F. Sander to olve loss of all parts of one chromosome, and dies on the chromosomes of Trillium by G. B. son and H. B. Newcombe gave data which cannot dily be fitted to any existing theory of crossing r but suggest a new partial hypothesis.

Features of the morphology of the circulatory tem of Amia, particularly in relation to an air-athing mechanism, were described by V. C. nne-Edwards, and the presence of a vessel of tal nature connecting the hypophysis and the othalmus in the frog was reported by E. Horne igie. The latter also demonstrated wide and portant differences in the vascular richness of hypothalamic centres in the rat. Various studies on the white whale were reported by V. D. Vladykov, who also discussed sexual dimorphism in the speckled trout. F. E. J. Fry had a paper on density of lake trout populations. An account of differential growth rates and of regeneration in the hind limb of the frog was offered by A. Emerson Warren. A study of temperature relations of the numerous species of midges (Chironomidæ) occurring in a lake was described by R. B. Miller.

B. P. Babkin and associates showed that ergosterol and parathyroid hormone effect gastric secretion in the dog chiefly by depressing its nervous phase. Early cessation of growth in rats on a rich fat diet was found by R. G. Sinclair and traced to the masking or suppression of synthesis of essential fatty acids. The effect of guaiacols on the respiratory passages was described by E. M. Boyd. Authentic notochordal tissue in a dermoid cyst of the ovary was reported by J. L. Riopelle. The structure and development of certain renal tumours led P. Masson to believe that the metanephros is not mesodermal but is derived from the neural crest; while his associate, P. Simard, found a constant neuroinsular complex in the mammalian apparatus. Drs. A. Scott and A. M. Fisher gave an account of the effects of certain chemicals in inactivating insulin and showed by moving picture film that each insulin crystal has two parallel square surfaces relatively close together, connected by four oblique quadrilateral surfaces. James Craigie showed that the Guarnieri inclusion bodies are probably not the intracellular colonies of a virus. The chemotactic attraction of staphylococci for leucocytes from mouse spleen was found by J. W. Stevenson and G. B. Reed to vary inversely with pathogenicity, while Alma Howard reported an inverse relationship between chiasma frequency in chromosomes and susceptibility to mammary gland carcinoma in mice.

THE AGRICULTURAL EDUCATION ASSOCIATION

Annual Conference at Belfast

HAT science can do much to help agriculture was the theme of several speakers at the Annual nference of the Agricultural Education Association ich was recently held at Belfast. Both Lord igavon (Prime Minister) and Sir Basil Brooke inister of Agriculture) referred with pride to the ievements of the Education and Research Divisions the Northern Ireland Government at the official ner of welcome, and reiterated the opinion that cation, both general and technical, is a sound estment. The Association, which met under the irmanship of Mr. W. B. Mercer, had a long pro-mme of scientific papers, interspersed with visits the Agricultural Research Institute at Hills-rough, with its experimental farm of 500 acres, Plant Breeding Station and Veterinary Research boratory at Stormont, and farms of the Irish Peat velopment Company at Maghery.

Dr. H. H. Corner directed attention to recent work 'pine' disease in sheep, which he declared was valent in the highlands of Scotland, the border counties, parts of Wales and in Devonshire. 'Pine' is an anæmic wasting disease due to a condition in which the iron of the food cannot be utilized by the blood: the presence of numerous parasitic intestinal worms is a secondary condition. Following the success of Underwood in Australia, who in 1934 showed that cobalt was the potent element in the utilization of iron compounds in enzootic marasmus, cobalt was tried in the treatment of 'pine' in the Cheviot region with great success. One ounce of cobalt chloride sprayed into and well mixed with one hundredweight each of steamed bone flour, and common salt, provided an easy means of preventing the disease, for the mixture could be set out in boxes for the animals to eat whenever they felt inclined. The cost was twopence a sheep per year.

Mr. James Mackintosh, as the result of two years experimental work with large numbers of cows in the south of England, suggested that a 20 per cent reduction might safely be made in the amount of protein now being fed to dairy cows. He suggested a standard of 0·5 lb. protein equivalent per 10 lb. of milk of average quality as a safe standard for farm practice.

Prof. R. G. Baskett, in a paper dealing with the firmness of fat in bacon pigs, stated that the back fat of pigs receiving de-germed maize meal had a significantly lower iodine value than that of pigs receiving half their ration in the form of maize meal.

Mr. H. Trefor Jones, in a paper on smoke pollution, said that in a town the size of Leeds domestic chimneys alone contribute to the atmosphere the equivalent of nearly a ton of sulphuric acid per acre per annum : in the industrial districts of the West Riding of Yorkshire, however, the sulphurous fumes are contributed chiefly by industrial chimneys and smouldering pit heaps. Most of the damage to crops is done during the dormant season : winter-sown crops like wheat and winter vegetables are the chief sufferers, whilst it is unsafe to spray potatoes with copper preparations even under conditions of mild pollution. In confirming or disproving cases of alleged smoke damage, and in explaining differences in productivity of the various parts of affected fields, the estimation of the sulphate content in the soil had proved very useful. Sulphate figures in excess of 0·020 per cent for grassland, and 0·030 per cent for arable land indicate smoke pollution.

Prof. S. P. Mercer had a good word to say for Yorkshire fog grass under certain conditions in Northern Ireland, advocated shorter leys combi with August sowing, and stated that rushes could very largely controlled by two cuttings a year two successive seasons. Dr. A. E. Muskett descri a laboratory method which allows seed disinfecta to be tested for efficiency in ten days at any tim the year. Radiation for 20 minutes with a qu mercury vapour lamp is used to promote sporulat of the fungus, thus making easier the examinat of the seeds at the end of the test. Dr. J. Car stated that until recently eelworms had not bee serious pest in Eire, but that root eelworm of potat was spreading and that the bulb strain of *Anguillul dipsaci* was beginning to attack onions, a crop wh during the last few years had undergone a remarka increase in Eire. Mr. R. Chamberlain described extraordinary but successful measures adopted Northern Ireland to stamp out the chrysanthem midge, measures which included the scheduling an area within which no living chrysanthemum pl could be kept, and the intensive inspection of premises in the area.

Other papers read at the meeting included c tributions on aspects of education by Mr. S. J. Wri and Mr. J. Getty : a paper on the flax-grow industry, by Mr. W. J. Megaw, peat land recla tion, by Mr. J. C. Baird, and a general acco of the agriculture of Northern Ireland by Mr. Morrison.

UNION BETWEEN HOST AND PARASITE IN HIGHER PLANTS

On this subject, Schumacher and Halbsguth have recently published an interesting and suggestive paper[1]. Their observations are based on extensive studies of species of Cuscuta and Orobanche on a wide range of host plants ; with the union of Cuscuta and its host, particularly, they have made use of techniques which permit the recognition of protoplasmic connexions, usually freezing the material, cutting on the sliding microtome and then transferring immediately to iodine potassium-iodide solution. Afterwards the walls were swollen and the connexions stained by a modification of Meyer's pyoctannin method.

In all cases they find (contrary to some earlier observations of Mrs. Thoday[2]) no direct connexion between the sieve-tubes of host and parasite ; the sieve-tubes of the parasite, indeed, are not found differentiated in the close neighbourhood of the point of union in the haustorium. From the haustorium, in Cuscuta, hypha-like cells ramify from the parasite penetrating the phloem tissue ; where these cells end in the neighbourhood of a sieve-tube they may develop a comb-like expansion of which the teeth close on the sieve-tube, so that these cells make very good contact with the sieve-tube, of which the wall is often much compressed. In the walls of these hyphæ, which are rich in protoplasm and often multinucleate, very numerous plasmodesma-like structures are found which seem to end free on their surface, but these 'plasmodesma' are never found on the comb-like ends, which seem definitely constructed to facilitate exchange between host sieve-tube and parasite.

In Orobanche these hypha-like cells are usually replaced by a densely plasmatic tissue, with prominent, usually single, nuclei ; these cells mult rapidly, they surround and compress and fin obliterate many of the sieve-tubes ; but the sieve-t up to the point of obliteration remains full of conte and presumably continues to transfer material fr host to this secretory type of haustorial tissue.

The authors conclude that their observati suggest that the transfer of food from host to para must take place across the walls of contiguous c the permeability of host sieve-tube presuma increasing, whilst the absorptive properties of haustorial secretory tissues may also be accentua at the point of union. The distribution of the pr plasmic connexions suggests that food transfer is their role. It is argued they may help the invad haustorial cells to orientate themselves in the host a in accordance with such perceptive functions, authors record the presence of similar structure the outer wall of epidermal cells, notably of tend But their figures suggest that these structures rather large for typical protoplasmic connexions it must be left for further work to clear up possible correlation of these epidermal features w plasmodesma or, on the other hand, with the w secreting channels described by Dous and Zieg speck[3]. These vertical wax-secreting channels deserve further scrutiny in view of Madeleine Mey observations[4] that the wax distribution suggests movement along horizontal channels in the cutini layers of the outer wall.

NEW FORENSIC SCIENCE LABORATORY

THE new Home Office Laboratory at Preston was opened on July 27 by Mr. A. L. Dixon, sistant Under-Secretary of State of the Home partment. The staff and equipment are provided the Home Office, which also meets the running sts during the initial period. The accommodation s been provided by the Lancashire Standing Joint mmittee. The Laboratory will serve the North-estern Area, which includes Lancashire, Westmornd and Cumberland and Cheshire.

The new Laboratory is conveniently arranged on e floor. The administrative offices are arranged a central hall, from which the various laboratory ctions are readily accessible. The Laboratory is rnished with modern equipment for carrying out emical (including microchemical), physical and ological investigations. There is also a fully uipped photographic section, including apparatus r microphotographic work.

This is the fourth laboratory to be established, hers being at Birmingham, Cardiff and Nottingm. Each laboratory is equipped to cover the range work which would satisfy all general requirements, it it would be impossible to equip each laboratory cover every possible case. This aspect is, however, rgely met by giving each laboratory some special ction, and in the case of the laboratory at Preston, e provision for dealing with chemistry problems made as complete as is reasonably possible. Thus reciprocal arrangements between these forensic ience laboratories (and in special cases certain overnment laboratories) it is possible to cover actically every phase of the work.

The principal function of the Laboratory is to give ientific assistance in the detection of crime to the lice in the area served by the Laboratory. The lice, however, have no control over the work hich goes on in the Laboratory; that work is solely der the control of the Director. He has only one ing to do—to find out what the various specimens bmitted (and in some cases his observations at the ene of crime) reveal from the scientific point of ew. It may well be that the results completely gative the police case and favour the defence. That no concern of the Director; he will state his findgs, which will be available to both sides.

In addition to the purely laboratory work, it is rt of the work of the Director to organize courses instruction which are available to the various tective forces in the area. This course includes e careful collection and preservation of materials be submitted to the Laboratory for examinaon.

The Laboratory, therefore, includes a museum in hich exhibits from various typical crimes will be llected and used for instructional purposes. lthough the new buildings have only been recently ened, the Laboratory was first started in September 938 in temporary premises with Dr. J. B. Firth as rector, and in this interim period on no less than 40 occasions have materials been submitted for amination and some 556 exhibits examined. These gures themselves will indicate in some measure that e new Laboratory with its more complete staff and uipment will be a great asset to the area which it designed to serve.

J. B. F.

SCIENCE NEWS A CENTURY AGO

Drainage of Lands by Steam Power

THE *Gentleman's Magazine* of August 1839 contains the following information: "The drainage of land by steam power has been extensively adopted in the fens of Lincolnshire, Cambridgeshire and Bedfordshire, and with immense advantage. A steam engine of ten horse-power has been found sufficient to drain a district comprising a thousand acres of land, and the water can always be kept down to any given distance below the plants. If the rainfall is excessive, the water is thrown off by the engine; if the weather is dry, the sluices can be opened and the water let in from the river. The engines are required to work four months in the twelve, at intervals varying with the season; where the districts are large, the expense of drainage by steam power is about 2*s.* 6*d.* per acre."

The Travels of J. D. Forbes in 1839

EARLY in August 1839, J. D. Forbes returned to Edinburgh after spending three months in south-east France, Switzerland and Italy. On his way south he visited Paris, meeting Arago, Cauchy, Elie de Beaumont and Niepce, and was particularly interested in Daguerre's pictures. He then travelled south by way of Dijon, Chalons and Lyons on the way to the department of Ardèche. From Montpezat he wrote of the district that "in a geological sense it is interesting in the highest degree, and I have four or five craters, just as well-defined and as recent-looking as Vesuvius, within a day's walk. . . . There are deep granite valleys divided by serrated mountains, through which here and there a cindery volcano thrusts his roasted head, while the valleys are clothed with chestnut and mulberry trees in the most exquisite manner". On July 5 he made an investigation of a meteorite which fell on June 15, 1821, "one of the very few which have fallen so near to intellegent spectators as actually to endanger their lives".

From the volcanoes of Auvergne, Forbes proceeded to Marseilles and then turned north to explore the little-frequented valleys around Monte Viso on the borders of Piedmont. He visited the village of St. Veran, 6591 ft. above sea-level, "the highest in Europe, except that of Soglio in the Tyrol", and attempted the circuit of Monte Viso. From these excursions he returned to Grenoble, and then having visited a brother at Geneva he travelled through some of the unknown valleys to the south, and then by way of Cogne and Ponte he reached Turin. On August 2 he visited the astronomer Plana, "overwhelmed with official engagements", and on the following day the geologist Sismondi.

Kent Zoological and Botanical Gardens

ON Thursday, August 8, 1839, "a party of citizens visited this delightful spot in a steamer, when about 650 gentlemen and ladies were regaled with a dejeuner, under a spacious pavilion erected in the gardens for the occasion. . . . The gardens are those at Rosherville near Gravesend. This piece of land, or the greater portion of it, consisting of seventeen acres, was taken into its hands by a company of gentlemen more than a year since, and by them it was made the object of a most extensive plan for the securing of its natural beauties and adding to it new and unusual attractions. . . . Clever use has been made of the excavation into the chalk cliffs . . . a further advance in the valley conducts to the botanical beds where it is intended to cultivate the rarest plants and flowers which the climate will allow. . . . Immediately next the perpendicular cliffs of these two divisions arrangements are to be made and are now in progress for the reception of wild beasts, birds and sea-fowl, etc." (*Mechanic and Chemist.*)

Thomas Tredgold

Tredgold, one of the founders of engineering theory and the author of the well-known definition of civil engineering embodied in the charter of the Institution of Civil Engineers, died in January 1829 at forty years of age, worn out by his exertions.

On August 10, 1839, the *Mechanics' Magazine* said, "To architects, engineers and persons concerned in any department of building the name of Tredgold must not only be familiar, but likewise respected and valued, and it is presumed not less so by many individuals in the higher walks of life. To all such it must be a matter of painful interest to be informed that the family of such a highly gifted man and martyr to science, consisting of an aged mother, two daughters in extremely delicate health, and a son of about thirteen years of age, are in very dependent circumstances. His friends have long cherished the hope that long before this time—for it is now ten years since his death—their situation might have attracted the favourable notice of government; but as this has not been the case, Mr. Habershon, one of his early friends and his biographer, with John Donkin, Esq., his joint executor, have commenced a subscription in furtherance of this laudable object."

Discovery of a Mammoth's Tusk

The issue of the *Athenæum* of August 10, 1839, states that at a meeting of the Bristol Philosophical Society "Dr. Fairbrother exhibited the tusk of a mammoth which had been found on the line of the Great Western Railway, near the spot where the city boundary crosses the line . . . in the lower part of a bed of gravel which reposes upon red sandy and marly beds, forming a part of the 'New Red Sandstone' formation. Its length is about 5½ feet, its circumference varying from 21 to 10 inches. It is curved in a form nearly circular and occupies an arc of about 140 degrees. Mr. Stutchbury supposes it to be a part only of the original tusk, which was probably 9 feet in length."

APPOINTMENTS VACANT

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant II under the Ordnance Board, Woolwich—Secretary (S.E.3), Ministry of Supply, The Adelphi, W.C.2 (quoting Appts. 01/S E.3) (August 11).

Assistant I at Air Ministry Headquarters—Under-Secretary of State, Air Ministry (S2A/B8019), Berkeley Square House, Berkeley Square, W.1 (quoting Ref. No B.229) (August 11).

Temporary Assistants Grade III (Male) in the Meteorological Office—Under Secretary of State, S.2.B (Met.), Air Ministry, Adastral House, Kingsway, W.C.2 (August 14).

Assistant Lecturer in Organic Chemistry—Registrar, University College of the South-West, Exeter (August 19).

Chief Assistant in the Chemistry Department—The Secretary, Robert Gordon's Technical College, Aberdeen (August 26).

Librarian in the University of Cape Town—Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (September 8).

University Chair of Chemistry at the Royal Cancer Hospital (Free)—Academic Registrar, University of London, Senate House, W.C.1 (September 15).

Assistant Engineer for the Malayan Public Works Service—Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/5731).

CONSERVATION OF ANTIQUITIES IN BRITISH DEPENDENCIES

THE Trustees of the British Museum (Bloomsbury) are to be congratulated on the acquisition of the remarkably fine bronze head from outhern Nigeria, to which reference was made in NATURE of July 15, p. 106. Not only is this an utstanding example of the highly developed rtistic products of early West African culture, but lso it belongs to a class of objects to which dditions available for study in European collecions are likely to be restricted in number in uture. Since the beginning of the century, and rising possibly in a great measure from the publication of the bronzes and other artistic objects from Benin in the Pitt-Rivers collections, nterest in and appreciation of the merits of the arious schools of sculptural art native to African ulture has increased rapidly and become widespread. In consequence, a number of characteristic examples, and many of exceptional merit, have been brought to Europe by collectors. During the past twenty years it has been known that bronze heads of remarkable character have been found from time to time in the course of excavation at Ifé in the Yoruba country of Southern Nigeria; but the discovery there in 1938 of a number of such examples of the artistic skill of an ancient and forgotten people, of which this British Museum acquisition is one, has quickened interest in these and similar objects of "high antiquity, artistic merit, and uncertain cultural origin", and as a result has induced those n authority to take steps to secure that West Africa should not be denuded of such interesting and important relics of its past.

In January 1939 the Government of Nigeria made an Order in Council enabling the Governor of Nigeria to control the export of antique African sculptural works of art; and since then the native authority of Ifé has taken action to protect the antiquities in the area under its administration. Such interest on the part of a native administration suggests that the subsequent action of the Secretary of State for the Colonies, announced in "The Colonial Empire" (the statement recently issued with the estimates for 1939) by which he has instituted inquiries with a view to the enactment of legislation throughout West Africa to secure the protection of indigenous African objects of ethnological import or æsthetic interest, will receive strong backing from a quarter which might not have been anticipated. It should ensure that any legislation which may be framed as a result of the inquiry will not become a dead-letter.

It is interesting to note that the Colonial Office, which frequently in the past has been accused of inertia when matters of moment to the scientific pursuit of cultural studies have been at stake, is now ready to give due heed to their interest and importance when attention has been directed to them. In Mr. MacDonald's own words: "Wherever such discoveries have been made His Majesty's Government has a keen interest in revealing them, and in preserving them, both on account of their scientific and historical value to scholarship, and on account of the susceptibilities of the local people, who naturally tend to regard these evidences of their cultural origins with reverence and pride".

It is in accordance with this policy that the study of antiquities is fostered and their conservation has been taken actively in hand by the authorities in several of the dependencies under legislative enactment. In Palestine, for example, which for the student of early racial and cultural history, apart from its bearing on the origins of the Christian religion, now holds a foremost place among the regions of major interest and significance for scientific research, not only does the Government direct the course of investigation by the exercise of its authority, acting under skilled advice, but also through the Department of Antiquities is itself engaged in investigation. In addition to the archæological work which has been carried out under licence, the study of the past history of Palestine has benefited by the activities of the Department of Antiquities in the field.

The importance of Palestine in the historic development of modern civilization naturally tends to attract to it investigators from outside, drawn from all parts of the world; and Jerusalem, equipped as it is with University, Antiquities Department, and the headquarters of several national schools of archæological research, since the War, and since the termination of the British mandate in Iraq, has become by far the most important centre of archæological interest under British jurisdiction. It is, however, by no means the only one; and if it were only possible to ensure more adequate financial provision, both Malta and Cyprus in their respective fields of archæological and historical interest might make a fair bid to become not unworthy rivals of the Holy Land. In Malta in particular, remarkable prehistoric remains and culture present a number of problems to the archæologist, which still await solution. Here a notable step in advance has been taken by the foundation of a professorship in archæology at the Royal University of Malta, which it is hoped, in the words of Mr. MacDonald's report, "will prove a starting point for a more exhaustive development of Malta's archæological wealth". A survey of the monuments of the island is projected. This is a measure which has been too long delayed; and although the visitor to the island, who views the remarkable prehistoric structures which form one of its attractions and examines the archæological collections in the Museum, will appreciate the devoted service to archæological studies in Malta over many years of the late Sir Th. Zammit, the net result for the discerning is an uneasy feeling that too little support has been given to the investigation of culture that in its way is unique. It is indeed t be hoped that a better day is dawning. M MacDonald announces that the curator of th archæological section of the Museum has been o study leave in Europe, and after working on sit in England is proceeding to Rome and Athens.

Cyprus, an island rich in historic association as it is in antiquities, has in the past been muc hampered by financial considerations; and thes notwithstanding assistance from private sourc interested in the past history of the island, hav not been entirely overcome. The work of th preservation of the ancient monuments of Cypru nevertheless continues. In addition to the amoun spent from the funds of the Government of Cypru generous assistance has been given towards th work by Lord Mersey's Cyprus Committee and b the Carnegie Corporation. Among the mo important of the monuments to which attentio has been given are the Castle of St. Hilario Bellapais Abbey, and the fortifications of Famagusta. In this work the Cyprus authorities hav had the co-operation of the Office of Works, a official having been seconded from England to th Cyprus Department of Antiquities as superintendent of works, who has trained a Cypriot official to undertake this function after his ow return to England.

In the conservation of antiquities, however anything approaching safety is to be won only a the price of constant vigilance. In this connexion it is interesting to find that in *Antiquity* of June the editor, in directing the attention of his reader to a communication from Mr. Stewart Perowne dealing with two ancient city sites of remarkabl archæological interest examined by him in th Aden Protectorate, urges strongly the need fo the appointment, without delay, of a Director o Antiquities for the Protectorate. He supports hi argument by reference to the importance fo archæological studies of this area, as indicate not only in the results recorded by Mr. Perowne as well as those obtained by Miss G. Caton Thompson, Miss E. Gardner, Miss Freya Stark and others but also by pointing out the imminent dangers o spoliation, if future exploration is not properly supervised, and adequate measures are not taken to protect the monuments and house the smalle finds of archæological research. There can be n question that the editor of *Antiquity* is right i thinking that archæological opinion in Great Britain is with him in this matter.

THE CASE FOR LEY FARMING

The Plough-Up Policy and Ley Farming
By Prof. Sir George Stapledon. Pp. 170. (London: Faber and Faber, Ltd., 1939.) 2*s.* 6*d.* net.

THE alternate husbandry system of farming has been widely practised in the parts of Britain with high and well-distributed rainfall for many years, but its spread to the more southerly parts f the country has been very slow. Until wild white clover seed and basic slag became available in sufficient quantity and at reasonable prices ley farming was not, in fact, suitable for the drier districts, because of the slow establishment of he leys; it must be remembered that it is only during the last twenty years that these commodities have become readily available. There have been many advocates in recent years for the wider spread of alternate husbandry; but the leader in this campaign has undoubtedly been Sir George Stapledon. Now that the movement has suddenly eceived the great stimulus of the Government subsidy for ploughing up pasture and derelict land, t is only fitting that he should issue a statement of the case for ley farming and a description of the methods necessary for success. This book covers the ground admirably, for not only are the wider aspects discussed but also details of manuring and cultivating, seed mixtures and seed production, even rabbits and moles and all the new problems which present themselves to the farmer adopting alternate husbandry.

Great emphasis is placed throughout the book on the building up of fertility. This indeed may be said to be the central thesis, and it makes the work especially valuable as a corrective to ideas very generally prevalent. The Government subsidy s clearly an emergency measure, designed to render a greater area fit to carry arable crops if the need should arise; the object is to persuade the farmer to take the first step towards cashing the fertility which may be stored up in land which has not carried arable crops for seven years or more. If the land has been under good grass, including a due amount of clover, and has been sufficiently grazed over a long period it will certainly be in a fertile condition; but much of the area that will be broken up is in a semi-derelict state and is in no form to produce good arable crops. It may be that Sir George Stapledon has devoted less of his book to the former class than its area merits, but most writers and speakers do the reverse, so that this work will do much to restore balance to the general view of the problem. Sir George Stapledon is an unrivalled authority on the farming of the poorest types of land, and he looks further ahead than the immediate future; he does not think so much of producing human food from accumulated reserves (which may not exist) as of the steady improvement of the land. Thus he does not urge the immediate growing of corn on poor land, but the sowing of short leys, including crucifers as well as grasses and clovers; he insists particularly on the value of Italian rye grass for grazing in the early stages of improvement.

It might be thought that the plough-up policy will find its greatest scope in the grassland districts, but there the equipment and knowledge for arable cultivation are sadly lacking: in the drier, eastern half of the country facilities already exist and a wide extension of ley farming may be expected. Most of Sir George Stapledon's work has been done in the west and some modification of methods may be desirable in the east. Aberystwyth has achieved great fame by its breeding of new strains of grasses and clovers; but the suitability of all these strains for drier conditions has not yet been adequately tested. The seeds mixtures recommended in this book, however, do not consist solely of the new Aberystwyth strains, the general advice being to blend them with the cheaper commercial strains. Where there is adequate rainfall the sowing of long leys on bare ground, rather than under a cover crop, is sound practice, convincingly demonstrated by wonderful examples of new leys at Cahn Hill and elsewhere; a luxuriant growth of leafy herbage is obtained in the first summer and it cannot be said that a year has been lost. But in a droughty summer, such as is common in the east of the country, there is very poor growth during the first summer, and lack of ground-cover invites the ingress of weeds. Uncertain rainfall makes it difficult to plan grazing far ahead and in drier districts there seems little future for special purpose leys, as recommended in this book; that greater efficiency can be got from them cannot be denied, but extreme variation in growth from year to year will probably make most farmers aim for a good all-round pasture, suitable for hay or for grazing at various times of the year as the exigencies of the moment may require.

It seems incredible that a book containing so much valuable material and one so stimulating can have been written and published in the short time since the Government subsidy for ploughing-up was announced; despite the rush in which the work must have been done there are very few ambiguities or misprints and the style is Sir George Stapledon's usual clear and bracing one. In his preface he promises his readers a "proper book" on ley farming, written at his leisure; that will be eagerly awaited, but meanwhile the prese book will prove extremely valuable. It very easy to read, definitely practical throug out, and has appeared at a most opportu moment.

THE LEADER TO PERFECT HEALTH

The Englishman's Food
A History of Five Centuries of English Diet. By Prof. J. C. Drummond and Anne Wilbraham. Pp. 574+16 plates. (London: Jonathan Cape, Ltd., 1939.) 12*s*. 6*d*. net.

DIET is neither frivolous knowledge nor a curious science; it is the leader to perfect health. So, in similar words, wrote Thomas Muffett in 1655; the sentiments are as true to-day as then, when at long last the subject of diet is beginning to be understood.

A picture of the changing character of the English diet during the past five centuries against a background of social and economic history would have been of absorbing interest if compiled by a mere historian. It gains greatly in definition and is much enhanced in its educative value when the author, or one of them, is among the most knowledgeable experts of the modern school of dietetics, so that the reader is assured of higher criticism of an unusual degree of scientific accuracy interspersed among the historical facts on almost every page.

All through history and in all lands the rich have eaten too much and the poor too little. In the light of modern knowledge what matters most is whether that food has been of the right kind to combat disease, and perhaps it is from this point of view that the book is most interesting. It is divided into five periods, covering Tudor England and the four subsequent centuries: for each of these there is information relating to the meals of the people, to their health, with special reference to scurvy and rickets and to other pertinent matters.

In Tudor times, according to foreign visitors, the Englishman of every class fed better than his counterpart on the Continent. The peasants suffered badly when harvests failed, but in good years they were well nourished.

In the seventeenth century, men who had made fortunes out of trading ventures, in particular the East India Company, invested in land, and farming became a national concern. Previously the profits of the wool trade had been so tempting that even arable land had been sacrificed to grazing, bringin about a local shortage of corn; but now throug out the century the acreage under corn steadil increased, bringing down the price to 27*s*. a quart so that bread was cheap, though there were, course, disturbing fluctuations in times of ba harvest.

Farmers began to grow turnips and learnt ho to store them during the winter packed in dry so or sand. About 1664 an effort was made to encourage the cultivation of potatoes, which ha already become so popular in Ireland and wer rapidly forming the staple food of the peasantr Fellows of the Royal Society were asked to plan the tubers in order to have a cheap food available fc the necessitous poor. The art of gardening developed rapidly in England, and fruit and vegetable became available in greater variety and quantit as witnessed by Evelyn's Diary. Very little progress was made in meat production, and much the stock was slaughtered on the approach winter.

In the eighteenth century, the rapid growth the towns brought new problems partly connecte with transport over bad roads, and it was not unt canals were constructed in the latter half of th century that the problem was eased. Foodstuf were required on a scale larger than they coul be brought to the towns and there was a marke deterioration in the quality, particularly in thos likely to be bought by the poorer people. Th trade in food began to be commercialized. Th public demand for a white bread led to the additio of alum to flour and other grosser forms of adulteration. Meat came slowly to the towns, being sol from fair to fair and coming on foot even all th way from Anglesey to London. Before sale, cattl were kept in the vicinity of London and fattene for the city markets. Much of the meat wa tainted: young people were warned by D Truster to refrain from "smelling to the mea whilst on the fork". Fish and poultry also cam on the market.

England was opulent during the first half of th century and a rise in the standard of living of th working people was favoured both by the cheapnes food and the appearance of cheap fabrics, andles and other products of new industries within e reach of their purses. The picture changed on after the accession of George III; there was disastrous sequence of bad harvests from 1764 ntil 1775 and the wars with America and France nded to keep prices high.

In the nineteenth century, the conditions orsened so far as the poor man was concerned. the towns, during the first half of the century, e greater part of the nourishment came from read, potatoes and strong tea. The consumption f tea was ever increasing and was nearly 4 lb. er head in 1871. The drinking of large quantities f hot fluid tended to reduce the intake of other ore nutritious foods—a glass of cold beer would ave contained far more real food. There is a imilar problem in Norway to-day, where large uantities of hot 'black' coffee are drunk, so educing the consumption of milk.

In the rich man's house the same period witessed the growth in popularity of the typical nglish breakfast which has lasted a century, hough there are signs that it is to-day being bandoned.

The nineteenth century also saw a deterioration n physique—at least this is the grim heading of hapter 22. The decline in breast-feeding of hildren, the prevalence of rickets, bad teeth, and bove all the displacement of grinding corn etween stones by roller mills, all had their effect. The intake of vitamin B dropped to one third of what it had been and there was widespread deficiency in other vitamins. In the authors' words, "the opening of the 20th Century saw malnutrition more rife in England than it had been since the great dearths of medieval and Tudor imes".

The few reformers, chief among whom was Seebohm Rowntree, found it difficult to awake the public conscience, and it was not until it was discovered during recruiting for the South African War, and still more during the Great War, how very large a percentage of would-be recruits was below the standard, that alarm was aroused. Even then other conditions were blamed in preference to defective diet. The discovery of the vitamins and the realization of their importance in the dietary gave an entirely new aspect to the science and practice of food and nutrition.

One of the chief post-War changes has been a general increase in the standard of living and a change from cereals to meat, milk, fruit and vegetables. The consumption of fruit and vegetables has nearly doubled, that of bread has halved. Latterly, progress has gone apace though there is still all to do: that it has been effective is demonstrated by the figures, announced at the time of writing, relating to the youths of 20–21 called up for the militia. The number of those in the lower categories is barely 10 per cent and some 20,000 more have been passed than was anticipated.

Generally speaking, Britain is becoming food conscious though not to the extent that prevails across the Atlantic. She owes much to her American cousins for what they are teaching her in this respect—indeed they have saved her from the somewhat tardy action of the medical profession.

This brief survey indicates the theme which runs through the book—it is elaborated at every turn with all kinds of information, and it would be possible to abstract from it the story of rickets or milk or other subject.

The book is stimulating beyond words; any reader of it must surely become a disciple for the cause of better feeding of our people. It is partly no doubt a question of poverty, but by no means entirely so.

Whilst much can and must be done by feeding school children, there is even more to be achieved by education. Probably, as a whole, the English are still the worst cooks and the most improvident housekeepers in Europe—a French working-class family was formerly said to be able to live on what its opposite number in England wasted, and there is still much truth in the gibe. The public must be made to realize that their health depends on their food and the way it is cooked and that health should have first call on the scanty pennies, even before the cinema or the football pools, on which ten million people spent £50 million pounds last year.

The man of science has shown a sad lack of imagination in his nomenclature of the vitamins. The use of A, B, C, D, E, etc., conveys nothing to the man in the street, who cannot possibly be expected to memorize their functions. They might at least be given names which indicate that they are antiscorbutic or antirickotic or provirility or something else. Their appreciation by the public is being retarded by the inability to talk about them by appropriate names. Our literary friends must cease their smiles at our impotence and come to our assistance—a nation which finds names for its racehorses should not be defeated by a few vitamins.

Drummond and Wilbraham will be widely read; it would be good for the nation if its sale exceeded that of the most popular novel. It should stimulate the body scientific to more work. We ought to know a lot more about the inner make-up of our foodstuffs—such as the difference between flesh, fish and fowl, the distribution of inorganics, on the chemical side; or the result of various deficiency factors on the biological side.

E. F. ARMSTRONG.

MAGNETIC OBSERVATIONS OF SUNSPOTS

Magnetic Observations of Sunspots, 1917-1924
By George E. Hale and Seth B. Nicholson. Part 1. Pp. iii + 91 + 8 plates. Part 2. Pp. ii + 692. (Papers of the Mount Wilson Observatory, Vol. 5, Parts 1 and 2.) (Washington, D.C.: Carnegie Institution (Publication No. 498), 1938.) 10 dollars.

IN these two volumes the late Dr. G. E. Hale and his colleague Dr. S. B. Nicholson give a connected account of the instrumental developments, and the observations, that proved the existence of strong local magnetic fields at the sun's surface. This account occupies fifty-seven pages of volume I. The remaining thirty-four pages contain tables giving the daily classification of every sunspot group observed at Mount Wilson from January 1, 1917, to January 1, 1925, and the maximum magnetic field-strength observed in each group. The second volume reproduces the Mount Wilson daily sketches of the sun's surface, showing the sunspot groups with their various members, and indicating the polarity and the approximate magnetic field-strength of these members. An examination of these sketches cannot but impress the reader with the wealth of results on sunspot magnetic fields that Hale and his fellow-workers have accumulated; they form a rich mine for theorists in solar physics, whose task in this field is, as yet, scarcely begun.

The general account of the work begins with a brief description of the state of solar observation, and of opinion on sunspots, in the eighteen-eighties, and of the successive steps that led Hale to develop the spectroheliograph and the tower telescope as a means of gathering something of "the rich harvest" which "lay open to the spectroscopist who would apply high dispersion to a study, not merely of sunlight, but of the light of isolated features of the sun's surface, such as sunspots". The foundation of the Mount Wilson Observatory gave him his opportunity to build first the 60-ft., and then the 150-ft. tower telescope, associated with auxiliary apparatus of the finest quality. The discovery by Hale and Ellerman of hydrogen vortices over sunspots impelled Hale to suggest, in 1908, that such vortices might be associated with electric currents, which would produce magnetic fields; he described how, by studying the polarization of the light, the Zeeman effect on the spectral lines of light from sunspots might be investigated, and announced his intention to make such observations.

Supported by laboratory investigations on the Zeeman effect, Hale's observations of the Zeem effect in sunspots were brilliantly successful: so a regular daily routine of magnetic observatio on sunspots was developed. The magnetic intensi and the direction of the magnetic lines of forc over different parts of spots and in the surroundi area, were determined. The first great discove was that sunspot groups usually consist of tw members, single or multiple, of opposite magnet polarity; "only about 15% of all groups observe fail to show at least a tendency towards bipol structure". At any one time (except near sunsp minimum) the polarity of all the leading spots bipolar groups in the northern hemisphere of th sun is in general the same, and opposite to th polarity of the leading spots in the souther hemisphere.

In 1913, at the first sunspot minimum after th observations had begun, came a second great an much more astonishing discovery: the system polarities of the spot-groups of the new cycle wa opposite to that of the spot-groups previousl observed: some error was suspected, but th scores of checks applied did not shake the validit of the evidence, and the reversal of polarity wa afterwards observed again in 1923 and 1933. Thi showed that the "old" sunspot cycle of abou eleven years is only half of the true 22-yea "magnetic sunspot cycle".

The magnetic field-strength was found to var roughly in proportion to the area of the sunspot from a maximum of about 4,000 gausses to value of the order 100 gausses in the smallest spot observable with present instruments. The field strength decreases, on the average, from a max mum at the centre of the umbra of a spot to a ver small value at points not far outside the oute boundary of the penumbra; at the spot-centr the lines of force are approximately radial, an thence they decline more and more until at th edge of the penumbra their inclination to the sun' surface is only 25° or less.

The authors conclude their general discussio with the following words: "Although man theoretical investigations of the internal state o stars like the sun have been made, including tw important papers by Emden and Bjerknes tha call for the existence of very different types o vortex phenomena, much time may elapse befor a satisfactory rational explanation of the magneti effects described in this volume can be found Such an explanation must take into account th striking phenomena of the solar atmosphere show the spectroscope, the spectroheliograph, and e spectrohelioscope, as well as the minute Zeeman ects that reveal the general magnetic field of e sun. Various geophysical phenomena, in-ding magnetic storms, the aurora, and those ociated with the transmission of radio messages, are also involved. Indeed, we may reasonably hope that some of the most fundamental questions of physics, chemistry, and astronomy may be illuminated by an intensive study, both observational and theoretical, of the problems of solar magnetism."

S. CHAPMAN.

THE CHINESE PEASANT

asant Life in China
Field Study of Country Life in the Yangtze
lley. By Dr. Hsiao-Tung Fei. Pp. xxvi + 300 +
plates. (London: George Routledge and Sons,
d., 1939.) 12s. 6d. net.

"I VENTURE to foretell," says Prof. Malinowski in opening his interesting preface to this book, hat 'Peasant Life in China' by Dr. Hsiao-Tung i will be counted as a landmark in the develop-ent of anthropological field-work and theory." ter he quotes Sir Denison Ross in a statement which he defines the position of this work in ientific literature and says "I regard this treatise quite exceptional. I know of no other work ich describes at first hand and with intimate derstanding the full story of life in a Chinese llage community. We have had works dealing ith statistics, economic studies and novels full of cal colour—but in no book have I found the swer to every enquiry, which the curious ranger might make". Commendation could not ll go further. These authorities, each selecting mention a quality and aspect of this piece of ld-work, which offers to him a special appeal, phasizes its two-fold interest for the reader. On e side the book is a first-rate study of social nditions, which though drawn from a limited ea, may be taken as applying with local modi-ations to a preponderance of the population of ina immediately before present Japanese aggres-on; on the other side it is a practical demon-ration of the contribution to be made by thropological studies in the field towards a anned approach to the solution of the problems, litical, social and administrative, which arise om cultural contacts, when Western civilization pinges on other, and in a material sense, less vanced forms of civilization.

Dr. Fei has taken as the scene of his operations aisienkung, a village south of Lake Tai in the angtze plain in eastern China. The country is a twork of canals and waterways, communications ing mainly by boat. The density of population aches the remarkable figure of 1,980 per square ile, this calculation, however, being based on nd surface only, whereas the gross density of e whole province (Kiangsu) is about 896 per square mile. The main industry is agriculture (rice cultivation) in a system in which the unit of social and economic organization is the expanded family. The returns from rice cultivation, over and above family subsistence requirements, were not adequate to meet family expenditure. They were supplemented by the production of silk as a domestic industry. The village, in fact, was in the centre of the silk-producing area of China. Unfortunately, the fall in world prices of silk has brought disaster to the industry, and the district, like many others, is face to face with the great agrarian problem of China, namely that the cultivation of the land, unsupplemented by other resources, will not support the peasant population.

Dr. Fei reviews in detail, "microscopically" as he puts it, the traditional social and economic system of this village as a working organism, and indicates the changes which have been forced upon it by disintegrating factors, both external—world economic and social conditions—and internal, due to efforts to ameliorate conditions within the village itself. Of these the most important is the endeavour to raise the standard of silk production and the institution of a village silk factory. Of the changes in custom due to the economic situation, the most striking is the curtailment, or complete cessation of all ceremonial and festive occasions over a period now of ten years duration. One result, for example, is not only the postponement of marriage to a later age, but also a modification of the character of the marriage system itself on the ground of the expense involved in the customary marriage ritual. The introduction of a co-operative factory and wages, which were previously unknown, have had a number of social repercussions, but not the least serious, both in the silk industry and in agriculture, where labour-saving methods of cultivation have been introduced, has been the creation of a class of unemployed labour, especially among the female population.

The village described by Dr. Fei has now been overwhelmed by the Japanese advance; but the author is nevertheless confident that China, as ever before, will eventually rise superior to her trials.

THE REALM OF BIOCHEMISTRY

(1) Outlines of Biochemistry: the Organic Chemistry and the Physicochemical Reactions of Biologically Important Compounds and Systems
By Prof. Ross Aiken Gortner. Second edition. Pp. xx+1017. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 30*s.* net.

(2) Organic and Bio-chemistry
By Prof. R. H. A. Plimmer. Sixth edition. Pp. x+623. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1938.) 21*s.* net.

(3) Biochemistry for Medical Students
By Dr. William Veale Thorpe. Pp. viii+457. (London: J. and A. Churchill, Ltd., 1938.) 12*s.* 6*d.*

IT is welcome to have under review at the same time three such excellent books on biochemistry dealing with different stages through which students in this science will be expected to pass.

The first two have passed the first edition, and Gortner's book is the second edition of the well-known text-book which has been brought up to date and amplified in accordance with modern needs.

The second book, by Plimmer, is the sixth edition of this well-known treatise and has also been amplified and brought up to date.

The third book is a student's text-book which has been written by a newcomer in this field, a deals with such matters as may be required the medical student.

Time was not so very long ago when biochem istry was treated as a section of physiology, a so far as science was concerned remained in relatio to organic chemistry a mass of empirical da which seemed to bear little or no relation one the other.

The books under review indicate that t physiological side of biochemistry is rapid diminishing in importance and the subject is bei based more and more strongly on organic chemist with its strictness of formulæ and diction. fact, there seems to be no hope of ever reachi any knowledge of what underlies the chemistry life unless biochemistry is approached from t pure science of organic chemistry. It is pleasa to note that in the three books under review t basis of organic chemistry is held in mind conti nuously and wherever possible the line followed that of established reason rather than of empir cism. Plimmer's book, and that by Gortner, a text-books of the science which deal in detail wit the whole subject; that by W. V. Thorpe contai a wealth of interesting detail. It restricts itself t that which the medical student requires, and t student who has acquired the knowledge containe in this book will not have laboured in vain.

J. F. T.

THE MANIPULATION OF GASES

Experimental Methods in Gas Reactions
By Dr. A. Farkas and Dr. H. W. Melville. Pp. xv+390. (London: Macmillan and Co., Ltd., 1939.) 30*s.* net.

THIS treatise will become a standard work and a necessary reference book for all physicists and chemists engaged in conducting experimental researches with gases. Its usefulness is enhanced by the fact that the authors have had actual practical experience with many of the devices and apparatus described, and are therefore well qualified to point out the limitations, defects and advantages of alternative methods of procedure. The arduous labour of collecting from scattered sources information hitherto imperfectly catalogued has resulted in a valuable contribution to science in a very practical form. The references are very numerous, the diagrams clear, and the printin especially of the formulæ, admirable. The math matical relations quoted in the text have in man cases been deduced from first principles, an theoretical questions of sufficient fundament importance have not been left unexplained.

In the preface the authors state: "The book designed mainly to give a reasonably complet account of the methods of investigating all typ of gaseous reactions together with sufficie theory, in order that there should be the minimu gap between theory and practice. While it intended that the beginner will benefit from t work, the text is arranged in such a way that may serve as a book of reference for those chemis and physicists engaged in dealing with g reactions, with high vacua, or with any investig ions where a knowledge of the preparation and handling of gases is required". They also explain hat there is no chapter on macro-gas analysis, he reason being that there are several excellent books on that subject.

The first chapter is devoted to an account of the elements of the kinetic theory of gases from he modern point of view. This happy combination of theory with practice—a characteristic of the work throughout—has very much enhanced the attractiveness of the reading. The second chapter gives an exhaustive account of apparatus for the control of pressure and temperature. It includes a description of the various types of vacuum pumps and pressure gauges, and has a section on aps, valves and lubricants. There is, however, no mention of the recent work in America and in Great Britain on phosphoric acid lubricants. This s the only omission of importance which we have found.

The third chapter deals with the preparation and analysis of gases, and includes directions for preparing the two forms of hydrogen and deuterium. The section on micro-gas analysis includes analysis by low-temperature distillation, and the estimation of *ortho-* and *para*-hydrogen, deuterium, etc. The fourth chapter, on photochemical technique, deals with absorption spectra, sources of radiation, methods of controlling radiation, light filters, and the measurement of radiation intensity.

The fifth and last chapter deals with the wide subject of experimental methods for the investigation of gas reactions. It includes explosive reactions, and optical methods of investigation, and the great variety of catalysts are described. The section on catalysts is particularly valuable in its examination of the different forms in which metallic catalysts may be used, and in its warnings on the dangers of poisoning and sintering.

Throughout the book useful guidance concerning manipulation and the construction of apparatus has been given. The authors are to be congratulated on a comprehensive and able piece of work.

D. L. C.

REGNUM ANIMALE

Caroli Linnaei Systema Naturae
A photographic Facsimile of the First Volume of the Tenth edition (1758). Regnum Animale. Pp. viii+824. (London: British Museum (Natural History), 1939.) 10*s*. 6*d*.

THE first volume of the tenth edition of Linnæus's "Systema Naturae", published in 1758, is now universally accepted by zoologists as the starting point for the application of the rule of priority in the scientific naming of animals. This particular edition was selected for the purpose because it was the first in which Linnæus consistently applied a binomial nomenclature to the species, while, on the other hand, it was the last to be published during his lifetime. It is probably safe to assume, however, that only a small minority of zoologists have ever had an opportunity of handling a copy of this somewhat rare book. Even the reprint of it published by the German Zoological Society in 1894 has long been out of print and seldom appears in catalogues of secondhand books. The Trustees of the British Museum have, therefore, rendered a service for which zoologists ought to be grateful in publishing a photographic facsimile of one of the copies in their library. The particular copy which has been used for the reproduction can be identified because care has been taken not to expunge the marginal notes and library stamps which it carries, a precaution that may prove one day to be important in the case of a work where much may turn on the spelling of a word or the position of a comma.

Even those who find the endless legal arguments as to the 'correct' names of animals little to their taste may discover much that is of interest in this old book. Linnæus, although he was much less of a zoologist than a botanist, had a broader conception of systematic zoology than we have to-day. His "Systema Naturae" was meant to be something more than a mere enumeration of species and their diagnostic characters; it was to be a summary of all that was known about them. Appended to many of the species are notes, condensed as only the Latin language can condense them, on the bionomics, ecology, distribution, and uses of the animals dealt with. For example, under "*Felis catus*" there is a delightful little paragraph giving (one imagines) a portrait of a privileged member of the family sitting by the stove in the old Linnæus house in the Botanic Garden at Uppsala, "tranquilla, ore molat, caudam erigit; excitata agillissima scandit, irata fremit . . . Murum Leo, in praedam intenta caudam movet . . . os instante tempestate manu lavat, dorsum in tenebris electrisat; in altum acta decedit in pedes" and then, when Linnæus has been kept awake at night, he writes "clamando rixandoque misere amat". But "odore ambrosiaco" must be ironical.

W. T. CALMAN.

THE ROYAL SWEDISH ACADEMY OF SCIENCE

BICENTENARY CELEBRATIONS

BY DR. J. RAMSBOTTOM, O.B.E., PRESIDENT OF THE LINNEAN SOCIETY

THE inaugural meeting of the Royal Swedish Academy of Science (Kungl. Svenska Vetenskapsakademien) took place on June 2, 1739, and the celebration of its bicentenary is to be held in Stockholm during September 23–25.

The Academy was founded mainly on the suggestion of Captain Mårten Triewald, who enlisted as supporters for a scientific academy publishing in Swedish, Jonas Alström, Baron Sten Carl Bjelke, Carl Wilhelm Cederhielm, Baron Anders Johan von Höpken and Carl Linnæus. A meeting was called at the Riddarhuset (House of Nobles) to form an "Economic Scientific Academy for the promotion of useful sciences"; the name "Swedish Academy of Science" was adopted, however, on the advice of Anders Celsius. The first president, chosen by lot, was Linnæus, then thirty-two years of age; the first secretary was von Höpken, an influential young nobleman who later filled in turn the highest offices of State. Von Höpken was responsible for drawing up the proposed statutes adopted at the inaugural meeting, and confirmed later by the King, who permitted "Royal" to be added to the title of the Academy. Linnæus was president only for the first four months and each of the original members succeeded him, sooner or later, in office. Under his presidency, thirty new members were elected, many of them men whose support he valued.

TWO OF THE STAMPS ISSUED BY THE SWEDISH POST OFFICE TO MARK THE BICENTENARY CELEBRATIONS OF THE ROYAL SWEDISH ACADEMY.

Subscriptions at first were in cash and in kind, Linnæus's presentation of a copy of his "Hortus Cliffortianus" and two Chinese books, on rice and silkworms, starting the present rich library. The printing of the *Transactions* was planned, with a device for the title-page of an old man planting a palm tree, and the inscription "För Efterkommande"; an original sketch for this is in th possession of the Linnean Society of London. O relinquishing office, Linnæus delivered a forma oration, "On Curiosities in Insects", setting a example followed by all succeeding presidents.

In 1747, the Academy was granted the privileg of publishing the Almanack and State Calendar, privilege several times renewed, and which is sti its chief source of income.

The Academy was immediately successful, an by 1746 its membership had reached one hundred a number to which the Swedish membership wa later formally limited and it was only this yea that it was agreed that in certain circumstance the number may be increased to one hundred an thirty. The prestige of the Academy led to th election of many of the most prominent men i the country, but though it was realized that muc was to be gained socially and financially by thi it was insisted upon that there should be real an active participation by all those elected. Th earliest statutes expressly ruled that if any membe "contrary to expectation" had not for two year sent in any work or done anything to promot the welfare of the Academy, such a member "bein superfluous" should, after two years, lose his sea and his vote in the deliberations. Obviously suc a rule was tricky to apply, and motions to effec it were occasionally shelved. However, five members were expelled in 1748, and 1783 saw the las of such expulsions.

Early in its history, the Academy undertook th building of an astronomical observatory for whic the city of Stockholm contributed the site and th State made a grant; the establishment wa removed to a new observatory at Saltsjöbaden ten miles south-east of Stockholm, in 1931. Peh Wilhelm Wargentin, the famous astronomer an statistician, became director of the Observatory o its completion in 1753; he had served as secretar of the Academy since 1749, and with an enormou capacity for work he was able to continue in offic until his death in 1783, having an assistant, provided from a private source, only in the last seve years.

After Wargentin's death, the Academy suffere a period of decline doubtless connected with th difficulty of finding an efficient and energeti successor. Various expedients were tried in orde to lighten the labours of the principal secretary ut it was not until the celebrated chemist Jöns akob Berzelius took on the post in 1818 that atisfactory progress was resumed.

Elections were made in the eighteenth century vithout regard to a properly balanced representaion of the different branches of learning. Different roposals were put forward to alter this, and in 1798 it was agreed to divide the members into even groups. The stated object of the Academy vas the promotion of useful sciences, and the first wo groups, National Economy and Agriculture and Trade and Commerce accounted for a quarter f the members. Berzelius with his organizing ability and broad views soon brought about hanges. In 1821 he had the two 'practical' groups ombined and the Natural Science and Medicine groups increased from four to seven with the object f making the Academy purely scientific. This lassification lasted until 1904, when a revision was ecessary owing to the task of awarding two of he Nobel prizes—the aim being to give more rominence to chemistry and physics. He also ad the rules for electing members revised. Each group had to submit "a well-thought-out and wellounded proposal" which was placed before a full meeting of the Academy. Berzelius was insistent hat it was the duty of members to keep in touch vith the progress of research, and the annual estival of the Academy (March 31) was chosen or the delivery of reports on the different branches f science. The reports during Berzelius's long enure of office were augmented and published, he imself being responsible for chemistry, and for hysics also until 1839. The series was translated nto French and German and was of the greatest mportance; but the task of preparation grew eavier, and shortly after Berzelius's death in 1848 t was found impossible to continue them. Not nly did Berzelius lay the foundation of the present onstitution of the Academy, but also by obtaining a fixed annual grant for the library and greatly xtending its exchanges insured its present minence.

Like all such national societies, the Academy ecame possessed of large museum collections, vhich gradually became too extensive for the uratorial facilities it could afford. When thereore Gustav von Paykull presented his large oological collections to the Crown in 1819, and he King entrusted their care to the Academy, he Academy presented its own zoological colections to the State. Thus began the Naturistoriska Riksmuseum which, though a national useum, is under the supervision of the Academy. n 1841 the botanical, mineralogical and ethnoraphical collections were also transferred to the useum. Recently the last-named have been eparated off as an independent institution—Statens etnografiska museum—which, however, is still supervised by the Academy.

A bequest by P. J. Bergius in 1790 of his estate of Bergielund just outside Stockholm for the purpose of establishing there a model botanical garden scarcely achieved its object because of lack of funds for ninety years or so. Then owing to the growth of Stockholm the area was included within the city boundaries with a consequent increase in value; the eighteen acres were sold and a site of more than sixty acres purchased about a mile north of the city and the present Bergian Garden established together with a School of Gardening. The president of the Academy for 1939–40, Prof. Robert E. Fries, is director of the Botanic Garden.

Among other institutions administered by the Academy are the Nobel Institute for Physical Chemistry set up in 1905 with S. A. Arrhenius as director until his death in 1927; this was replaced in 1933 by the Nobel Institute for Theoretical Physics with C. W. Oseen as director: the Kristineberg Marine Zoological Station, the Mittag-Leffler Foundation for Mathematics, the Physical Institute, the Abisko Natural Science Station and the Committee for the Protection of Nature.

The Academy usually meets twice monthly, except in summer, at Novra Djurgården, a district which is commonly known as Vetenskapsstaden (Science City) and which may be compared in some ways with South Kensington. The annual festival is traditionally held in the Riddarhuset, and is usually attended by members of the Royal Family.

To mark the celebrations, the Swedish Post Office has issued four special stamps, two with a portrait of Linnæus and two with that of Berzelius—one of each is illustrated here. The portrait of Linnæus is apparently taken from the Academy's painting by Roslin and that of Berzelius from the one by Södermark.

The preliminary programme announces that the delegates and guests will meet on Saturday afternoon, September 23, at the Academy building and afterwards visit the institutions at Vetenskapsstaden. In the evening there will be an informal dinner. On Sunday afternoon, the bicentenary festival will be held in the Stockholm Concert Hall in the presence of H.M. the King and other members of the Royal Family. In the evening there will be a banquet in the Stockholm Town Hall. On Monday the Stockholm Observatory at Saltsjöbaden will be visited, tea will be taken at the Royal Palace and in the evening there will be a gala performance at the Royal Opera House.

Delegates have been sent a pamphlet on the history of the Academy prepared by Dr. Arne Holmberg, the Academy's librarian. I have had free use of this in compiling the above account.

THE WYPERFELD (MALLEE) NATIONAL PARK, VICTORIA

By Sir James Barrett, C.B., C.M.G.

THE Wyperfeld National Park is situated about 300 miles north of Melbourne in the midst of the country known as the Mallee, which occupies about one fifth of the area of the State of Victoria. The soil of the Mallee varies greatly; but much of it, when cleared of the Mallee eucalypts, has proved excellent wheat country. The clearance was due to the invention of the stump jump plough and the roller. It varies greatly in quality, being in some places almost entirely sandy and in others fertile red soil. All of it is very liable to wind erosion, unless special precautions are taken to preserve both belts of eucalypts and some surface vegetation, and so far these precautions have not been taken in general.

At some geological period the whole of the area appears to have been a gulf of the sea into which such rivers as the Murray, the Murrumbidgee, the Goulburn and other Victorian rivers poured their waters, carrying with them silt from the Alps. This gulf has been filled up. The rivers have for the most part fallen to small proportion or are actually dying. I am informed that bores put down go through 200 feet of lake deposit before the marine deposits are reached.

The Wimmera River, once a large stream, running north from the Grampians, enters at Jeparit a large lake called Hindmarsh and then another—Lake Albacutya—and finally passes nort for many miles through the Park itself and lose itself in sandy country. It has flowed in this wa usually about once in fifteen to twenty years. saw it in 1922–23 when the water for a year o two covered the lower 12 feet of the giant eucalypt on the river bed; it gradually evaporated an became saline and then dried altogether. At th present time the only available water is from on well provided with a windmill which, so far, ha given a good supply.

The large eucalypts are found only in or near th river bed. The annual rainfall, which is capriciou is something less than 9 inches and the evaporatio is enormous. There are quite a number of ope spaces with good soil well grassed but flooded whe the river resumes control. It is on these areas tha the cattle, the emu and the kangaroo feed in th main but not exclusively. The sandhills ar enormous, but I have not seen any evidence of an considerable movement.

The biological interest of this arid region o 82,000 acres is the fact that it is well stocked wit animals which, since its reservation and with protection, have greatly increased. The black-face kangaroo, found only in the Mallee, is abundant emus are plentiful but constantly shift from plac to place. It is probably in Victoria the last hom of that wonderful bird—th mound builder, called the lowar which incubates its eggs in th vegetative centre of mound which it builds and which in on case I measured was 18 ft. in diameter and 4 ft. high (Fig. 2 The parents evidently watch th mounds but, after hatching, th young birds fend for themselve With protection they have increased in numbers and in thei fearlessness of man.

But the major interest whic led to the reservation was th fact that it is the home of vas numbers of the parrot and cockatoo family, which apparentl nest in the large eucalypts an feed in the desert away fro the river. The Regent parr and the Major Mitchell cock too, the disappearance of whic

FIG. 1.

WYPERFELD FROM ONE OF THE HIGHER SANDHILLS. *Eucalyptus rostrata* ON A FLAT NEAR THE DRIED-UP WATERCOURSES.

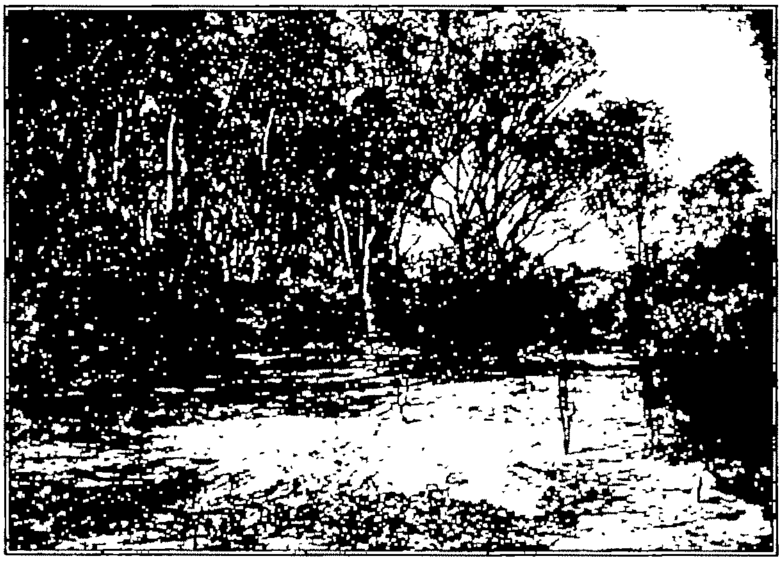

Fig. 2.

Eucalyptus rostratus WOOD WITH *Acacia* IN BACKGROUND AND LOWAN'S NEST IN FOREGROUND.

as feared, have become bundant.

The birds drink at the trough rovided at the well, but so far o one has seen the kangaroos t this source; yet a tame angaroo I have in Melbourne lrinks greedily. Precisely how hey obtain sufficient water in he Park is, so far, unknown to s.

Of reptiles there are only the tumpy tailed lizards, a few tree-limbing lizards, but rarely a nake.

I may add that during the ecent heat burst, the temperaure to the north of the Park eached 119° F. Many magpies lied, a few parrots were lost, but he kangaroos, though exhausted nd collapsed, managed to survive.

The Park is leased to a cattle grazier at a low ental, but in return he acts as curator and is well nformed of the habits of its inhabitants. A clause n the lease provides that if a fire occurs in the Park his lease may be cancelled. So far no fire has occurred, but during the recent disaster a fire outside the Park was just stopped on the boundary.

The profound interest of the Park lies in the act that in the arid though very beautiful reserve he animals have adapted themselves to these dry onditions and show no desire to leave it. It hould be added that no complete or adequate biological survey has yet been made. There are ndications that some of the smaller marsupials may be found. Such a survey can only be made by esidence in the Park and a careful search made, specially at night, with a powerful searchlight.

We are indebted to three Ministers of Land for the reservation, which was not easy to secure, namely, the late Mr. Owan, Mr. Bailey and the present Minister, Mr. Lind.

BOTANICAL CHARACTERISTICS

By Prof. J. S. Turner, University of Melbourne

The Park, so far as it has been investigated, seems to be composed of two distinct types of vegetation, each with its own soil environment. First, there is the vegetation along the outlet creek from Lake Hindmarsh. Along this creek is a chain of lakes, usually empty, of which Brambruk is one within the Park itself. Along these dried-up water courses there are two eucalyptus communities: 1) the red gum, *E. rostrata*, which is the more moisture-loving of the two; (2) the black box, *E. bicolor*. The forests formed of these trees are very open and the floor is grassed. Both communities are found elsewhere in Victoria.

The second main type of vegetation is of greater interest and constitutes what is locally known as 'desert'. It is made up of wind-blown sandhills of comparatively recent origin but not, at present, mobile. These sandhills are entirely distinct from the sand ridges found in the settled regions of the Mallee. In these more settled parts, the original vegetation was largely the Mallee eucalypts, but in the 'desert' these trees are much less frequent.

In spite of the inhospitable character of the sandhills and the very low rainfall, the 'desert' area carries a large number of typical Australian plants. The family Myrtaceæ is represented by Eucalyptus, Leprospermum and Melaleuca; Leguminosæ by Acacia; Proteaceæ by Hakea and Banksia; Epacridaceæ by Leucopogon and Astroloma; Casuarineæ by Casuarina; and Coniferæ by Callitris.

The sandhills are frequently capped by species of Callitris, *C. verrucosa* being probably the commonest. These pines are, however, dwarfed, and the sandhills cannot be compared to the pine ridges in other parts of the Mallee. Below the pines occur a large number of tall shrubs and small trees; for example, *Leptospermum coriaceum*, *Banksia ornata*, *Casuarina Muelleriana*, which last species has a restricted range but is abundant in the Park.

Acacia spinescens is a very spinous shrub. *Astroloma conostephioides* has conspicuous brilliant red flowers. The two genera Pimelea and Hibbertia, which are very widespread in Victoria, are both represented here by very handsome species, *P. stricta* and *H. virgata*. These two species differ from most of those in the Park, in that their leaves are not sclerophyllous. The vegetation does not nearly form a complete cover on the sandhills, but it is sufficient to prevent wind erosion.

As in deserts in other parts of the world, this area bears a large number of minute annuals with a very short life-cycle. The number of these species in Wyperfeld will probably be found to be very large. The family Compositæ is particularly well represented. *Toranthus Muelleri*, *Brachycome pachyptera* and *Gnaphalodes uliginosum* are all extremely minute annuals found in the Park. Most of these species spend a dry season as seeds and pass through their short life-cycles soon after periods of heavy rain, and they are consequently easily missed by investigators of the flora.

GEOLOGICAL CHARACTERISTICS

By Dr. E. S. Hills, University of Melbourne

The rocks of the Mallee are marine, estuarine, fluviatile and lacustrine sediments laid down in and near the margins of a former marine gulf during Cainozoic times. This marine bight, which has been named the Murray Gulf, came into existence in Oligocene times, and from then on to the end of the Pleistocene it was gradually filled with clays, limestones, marls and sands. The thickness of these ranges up to a total of more than 2,000 ft. and they rest upon a depressed basement of older rocks, chiefly Palæozoic granites, schists, sandstones and conglomerates, which have been penetrated in bores. The limestones, which are Miocene age, are overlain by impervious clays the Mallee, and are important aquifers for artesi and subartesian water.

The superficial deposits are sands, gypsum a local freshwater ostracodal limestones, of fluviati and lacustrine origin. The sandy soils deriv from these deposits have been heaped by the wi into long regular sand ridges, trending east-we with areas of irregularly arranged 'Jumbled' san hills in places. In their virgin state, these sa ridges are fixed by a cover of vegetation, but whe this has been cleared, extensive sand drift has sin taken place. There is evidence that the regul sand ridges, which have been formed under t action of the dominant westerly and north-wester winds, have grown in stages. Buried soil horizo of 'travertine' limestone indicate that periods relatively high rainfall have alternated with dri periods. The present (or immediate past) tin appears to be a relatively wet period.

Apart from the minor undulations due to t sand ridges, the surface of the Mallee exhibi broad ridges and troughs, some miles in widt the trend of which varies from north to nort west. These are of tectonic origin, reflecti buried faults or warps in the underlying bas ment complex. Uplift across the lower course the Murray resulted in the formation of lake which have now been trained, and in these a other old lake basins extensive deposits of gy sum, locally known as copi, were laid dow These now constitute an important source of th mineral.

OBITUARIES

Dr. W. J. Mayo

TO the surgeon, and especially to the surgeon in the United States of America, the death of Dr. W. J. Mayo on July 28 at the age of seventy-eight years is a major historical event. Born in 1861, in the State of Minnesota, he spent his life and did his work in the small country town of Rochester; and there with his brother Charles, who died two months ago (see NATURE of July 15, p. 103), he built up the Mayo Clinic the expansion of which has been very great. In early life he conceived the idea that patients could best be treated by groups of medical men among whom could be found specialists in every disorder. This idea was revolutionary at the time; and although in operation it may best be suited to American conditions, not only did it underly the practical success of the Mayo Clinic, but it has also influenced wider opinion because medical men from all over the world were attracted to the experiment. In Rochester was to be found an organization almost fanatically devoted to t interest of the patient, to the exclusion both financial considerations and of personal profession renown. For from the beginning of the clinic pa of its profits were set aside to be devoted to researc not only in clinical subjects and the fundament clinical sciences, but also in such related sciences chemistry and physics. The two brothers and the early collaborators deliberately sacrificed wealth and chose to regard as their reward the knowled that their Institution was making substantial co tributions to medical progress. As funds accumulate they were to expand their efforts, always governe by the same general principles, to postgradua education; and their system of training young me broadly and encouraging specialization only after sound basic experience has been watched wit interest by the medical academic world, and h frequently been utilized by medical schools both i America and in Europe; for one of the man xcellences of the clinic has been its readiness to xpound its technical methods and the results obtained by them to visitors of any nationality. There is no doubt that the inception and later the guidance of this great experiment in group practice were controlled by Dr. Mayo; and the success which has attended his aims stamps him as a man of singular vision, broad outlook, indomitable perseverance, possessed of administrative powers of the highest order.

In the practice of his craft, Dr. Mayo was in the first rank. His personality and sincerity at once gained and ever afterwards retained the confidence of his patients; as an operator he could be cautious or bold as the occasion demanded, and with his enormous experience and thought for individual patients those who worked with him came to rely mplicitly on his surgical judgment. His chief nterests lay in the surgery of the alimentary and biliary tracts, and to these he made many substantial contributions. He was sedulous in promoting the advancement of surgery in the United States, and to this end interested himself actively in the founding and governing of the American College of Surgeons and the American Surgical Association. This disnterested devotion to surgery was honoured by earned bodies all over the world.

As must men whose energies are devoted to the control of great enterprises, he kept himself somewhat apart. But he was a warmhearted and generous helper of his juniors, for he knew better than most, and lived to see himself right, that to justify his conceptions the organization which he built, almost with his own hands must live on after he relinquished active control.

J. R. LEARMONTH.

Prof. R. W. Reid

PROF. ROBERT W. REID, emeritus regius professor of anatomy in the University of Aberdeen, the Nestor among British anatomists, died in Aberdeen on July 28, aged eighty-eight years. He was born in the manse of Auchindoir, Aberdeenshire, in 1851, and after graduating in medicine in the University of Aberdeen, became demonstrator of anatomy in St. Thomas's Hospital, London, in 1873, being almost the first medical man to be attached to a London hospital as anatomist. In 1889, he succeeded Sir John Struthers as professor of anatomy in the University of Aberdeen. He held this chair for thirty-six years, retiring in 1925.

Reid was the sole survivor of the anatomists who founded the Anatomical Society in 1887; he became president of the Society in 1910. He was elected a fellow of the Royal Anthropological Institute in 1886. His first important contribution to anatomy was entitled "Observations on the Relation of the Principal Fissures and Convolutions of the Cerebrum to the Outer Surface of the Scalp"; this appeared in the *Lancet* of September 27, 1884, and it contains a description of a base line—spoken of to-day as "Reid's Base Line". Two other important papers on topographical anatomy were published by him in the *Journal of Anatomy*—one on the relationship of nerve roots to vertebral markings; the other on the position of the chief nerve trunks.

Soon after being appointed to Aberdeen, he established in connexion with his department an anthropological bureau to register the physical characters of the students who entered and to keep a record of their growth changes. Reports from the valuable data thus collected have appeared in the *Journal of the Royal Anthropological Institute*. Records are still being kept, and no doubt will provide the material for further papers dealing with the anthropology of the Scottish student. Another great service he rendered to the prehistory of Scotland by the preservation and study of the remains of the strange people who first appeared in Aberdeenshire early in the second millennium B.C. His own physical features were so similar to theirs that one had reason to regard him as a descendant of these early Bronze Age settlers in the north-east part of Scotland. The Anthropological Museum of the University of Aberdeen, in which these unique specimens are preserved, owes more to Prof. Reid than the "Illustrated Catalogue of Specimens from Prehistoric Interments found in the North East of Scotland" which he wrote in 1924. In acknowledgment of what he did for this Museum and for the University, his friends and pupils endowed a lectureship in connexion with it—known as the Reid Lectureship. He was the moving spirit and the purse-bearer—that brought into existence the Anatomical and Anthropological Society of the University of Aberdeen. In person he was retiring, almost morbidly modest, charitable and very hospitable.

Dr. W. A. Potts

DR. WILLIAM ALEXANDER POTTS, who died on July 23 in Birmingham at the age of seventy-three years, was a familiar figure to those interested in psychological medicine and latterly also to those interested in criminology.

Potts started his scientific career at the East Riding Mental Hospital, Beverley, but left this branch of work to go into general practice, where he remained for fully twenty years. After this he became medical adviser to the Birmingham Mental Deficiency Committee and so his more scientific side became concentrated on the mentally defective. Since 1919 he had been very helpful in an advisory capacity to the police courts in Birmingham, particularly when they were dealing with cases of mental deficiency. He was also medical adviser to the Barr Park Colony and consultant to the Royal Albert Institution. He was chairman of the Special Schools After-Care Committee in Birmingham. He carried out a considerable amount of work lecturing and teaching, and collaborated with Shuttleworth in his "Mentally Deficient Children".

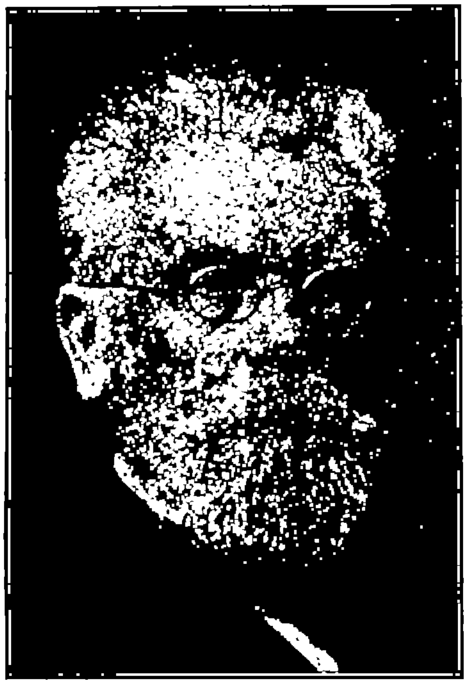
He was a most charming personality and always had a ready smile and a helping hand for the young man.

WE regret to announce the death of Mr. H. P. Hollis, a former president of the British Astronomical Association, on August 7, aged eighty-one years.

NEWS AND VIEWS

Prof. F. Vejdovský

DESPITE the disturbed political situation and international tension, Czech men of science and their friends intend, if possible, to celebrate next October the ninetieth birthday of one of Bohemia's most distinguished living sons, Prof. František Vejdovský, who was born on October 24, 1849. After studying at the Charles University of Prague, and already as a young man winning fame as a zoologist, he was elected professor of zoology, comparative anatomy and embryology in the Charles University in 1892, retiring as professor emeritus in 1921. During his long life, Vejdovský has not only been very active as a teacher and leader among Czech zoologists, he has also, by his own researches and those of his numerous pupils, contributed largely to the advancement of many different branches of zoology. His own work covers a very wide field, but it has dealt mainly with the morphology, development and systematics of various Invertebrata, and with cytology—especially spermatogenesis, fertilization and problems connected with the centrosome and the chromosomes. On these and other matters he has published some ten large treatises, and more than a hundred other memoirs in Czech, English, American, French and German periodicals.



PROF. F. VEJDOVSKÝ

IN his own country, Prof. Vejdovský has long been held in the highest esteem, and his accomplishments and his personal kindliness have endeared him to a wide circle of friends and correspondents abroad. Few men attain the age of ninety years, and fewe still can look back upon so long a lifetime spent i the wholehearted pursuit of science for its own sake Prof. Vejdovský has lived through the classica periods, of Darwinism and Mendelism, and ha actually seen the rise of modern cytology—to whi he contributed an honourable share—and he ha hitherto survived the prolonged ordeals which hi nation has suffered during this century. All tru men of science everywhere must therefore offer hi respectful congratulations on his approaching birthday, and wish him and his people that peace and future happiness which, by their steadfast devotion to science and civilization, they so richly deserve.

Petrus Camper, F.R.S. (1722-1789)

THE fifteenth volume of the *Opuscula Selecta Neerlandicorum de Arte Medica*, which has recently been published under the able editorship of Dr. B. W. T. Nuyens, of Amsterdam, contains the illustrated travel diaries in Dutch and English of the three visits to England made by Petrus Camper, who was not only one of the most eminent Dutch medical men in the second half of the eighteenth century, but was also a botanist, zoologist, mineralogist, palæontologist and draughtsman of distinction. The first visit, in 1749, three years after his qualification, was chiefly undertaken for the purpose of attending the lectures of William Smellie, the father of British gynæcology, and of taking lessons in drawing at the Royal Academy. During his stay in Great Britain he made the acquaintance of many of the leading scientific men of the day, including Sir Hans Sloane, Sir Joseph Banks, F. W. Herschel, John and William Hunter, John Smeaton, Mead and Cheselden. He attended the meetings of the Royal Society, of which he was made a fellow in 1750, visited the hospitals and museums and showed the keenest interest in contemporary scientific novelties. He did not confine his attention to London, but visited Oxford, Cambridge, Bath, Bristol and Birmingham, where he made the acquaintance of Withering and James Watt. In the next two visits which he paid in 1752, when he was professor at Franeker, and in 1785, a few years before his death, his energy and enthusiasm still appeared to be unabated, and his time was profitably spent in a congenial scientific atmosphere.

New Technical Branch for the Royal Air Force

OFFICIAL confirmation was given recently of a decision to form a separate technical specialist branch of the Royal Air Force. It has become increasingly obvious that, owing to the technical complexity of the problems relating to service aircraft and their equipment, it is necessary to allocate personnel to engineering and technical duties, allowing them to devote their whole time to such work and arranging various courses of training for them. Up to the present, the policy of the Royal Air Force has always been that all officers must enter the "General Duties Branch", and devote their time to a complete training in flying for, at least, many years of their time as junior officers. Later they can express a wish to take up specialization in technical work, but they are still required to maintain proficiency in flying. Thus the process of becoming a technical specialist is a slow one, and in a service in which the retiring age is, possibly necessarily, set fairly early, as flying is primarily a young man's job, the officer choosing these branches always finds himself at a disadvantage, either for promotion within the service, or in respect of his ability to obtain employment in the technical side of aviation upon retirement. Also the break in continuity of training and accumulation of experience is usually considered to be unwise, and many young engineers, both from the universities and works apprenticeships, have undoubtedly been deterred from entering the Royal Air Force by this reason.

In spite of the enthusiastic membership of the university air squadrons the number of technical graduates offering themselves for University Commissions in the Royal Air Force has always been relatively small. The new branch should remove these disadvantages. Entrants for commissions are now offered direct entry into technical work, without having to spend several years in acquiring proficiency in flying. They are to be recruited from university graduates in engineering or natural science, and student apprentices from works who have acquired theoretical knowledge up to a university degree standard. The retiring age limit may well now be extended, as the work is not that in which the younger man necessarily excels, in fact the older man would be superior by reason of his accumulated experience. Prospects of promotion should also now be greater as there must be senior administrative posts within the new department.

Further Archæological Excavation in Syria

Sir Leonard Woolley's third season of excavation on the ancient site of Allalakh at Atchana near Antioch, as anticipated, has enlarged and added further detail to the picture of a great meeting place of the civilizations of East and West at an entrance gate to western Asia; but at its close it held out promise of an even greater field of discovery still to be explored. Of this a glimpse may be afforded when the numerous cuneiform inscriptions retrieved in the season just past have been submitted to inspection. Sir Leonard in his preliminary report (*The Times*, August 2 and 3) opened with an account of the further excavation of the earlier palace, which preceded that of the fifteenth-century Hittite king, Nig-me-pa. This earlier building, cannot, Sir Leonard thinks, be much later than the time of Hammurabi, and he assigns it tentatively to the eighteenth century B.C. The structural features, which point to its use in part for administrative and business purposes, in part as a royal residence, convey the impression of a sense of dignity and propriety, combined with an unusual appreciation of space and air, particularly noticeable in the arrangement of the upper residential chambers, with a loggia giving an extensive view over the city, and an approach by newel stairs, of which the first two flights are nearly perfectly preserved. It was, however, from a private house of the fifteenth century that the much desired further evidence was obtained of the contact with Crete, for which mainly the excavation of Atchana was undertaken. This now took the form of a fresco, which is exactly similar to a scheme of decoration found at Knossos, and a 12-wick lamp in red porphyry in the form of the capital of a column, which at Knossos would be hailed, Sir Leonard says, as a typical, but unusually fine, example of Minoan art.

It was, however, towards the close of the season's work that the most striking discovery was made, which, as Sir Leonard says, "goes far to complete the picture of the ancient city of Allalakh". This was a temple, which throws light upon the religion of the people, and gives examples of their major arts. Though the clearance of this part of the site has only just begun, it is already evident that here are the superimposed remains of at least four temples, of which the latest may date to about 1200 B.C. and the earliest to the fifteenth century. They had been richly adorned with sculpture. Although as yet it has not been possible for Sir Leonard to give more than the most summary of accounts, the record of finds is amazing in both number and interest. Among the more arresting finds are the remarkable sculptured lions, the bronze spearhead, deemed to be a cult object, and most remarkable of all, the hidden statue of a king or god in white limestone with its fifty lines of cuneiform inscription, of which the decipherment will be awaited with keenest anticipation. Such a mass of evidence of the character of Hittite art, and of so early a date—at least of 1200 B.C. and possibly even of the fifteenth century—is indeed an unexpected, but more than welcome find.

Excavations at Ezion-Geber

Recent excavation at Tell el-Kheleifi on the Gulf of Aqabah, Sinai, by the American School of Oriental Research at Jerusalem, not only has confirmed the indications of the importance of this site in early times as a meeting place of a number of trade routes, afforded by investigations in 1938, but also has revealed that it was the centre of an extensive industry for the smelting and refining of copper and iron from the mines of the adjacent Arabah. The site has been identified with the great port of King Solomon, Ezion-Geber "which is by Elath on the shore of the Red Sea, in the land of Edom". No longer, however, does it stand by the sea. The prevailing northerly winds have brought sand to silt up the head of the gulf, so that the shore is now half a mile away. The importance of the city as a commercial centre was indicated in the first season's excavation by a number of finds, of which the most important is held to be a large broken jar, on which had been incised two letters belonging to the early South Arabic script. This is assigned by stratigraphic evidence to approximately the latter part of the eighth century B.C. The letters are the earliest known to be definitely datable from a scientifically controlled excavation. Dr. Nelson Glueck, director of the School, in a preliminary account of the excavations carried out in May–June, 1939 (*Illustrated London News* of August 5) records the discovery of an ingenious and complicated system of flues and channels in the thick and high walls of sun-dried brick of the first city, which is so constructed as to utilize the draught of the prevailing winds from the north for the furnaces of an elaborate complex of smelting and refining plant—the largest yet discovered in the ancient Near East. This system would appear to have been the governing factor in determining the site for the first city; and so well bonded were the bricks that many of the walls still stand almost at their original height after nearly three thousand years. Among smaller finds from the third city were Egyptian amulets, of which one was a small cat, a form characteristic of the cult of the goddess Bast of Bubastis, and another was the Uzat eye of Horus.

Jenner and Napoleon

At a recent meeting of the Section of the History of Medicine of the Royal Society of Medicine (*Proc. Roy. Soc. Med.*, **32**, 877; 1939), Dr. J. A. Nixon said that the world-wide eminence of Edward Jenner found no better illustration than his ability to secure the liberation of British prisoners from countries with which England was at war. One of the best known of these prisoners was the Earl of Yarmouth, the model of Thackeray's Marquess of Steyne and Disraeli's Marquess of Monmouth, on behalf of whom Jenner addressed in 1803 the following appeal to the National Institute of France: "The Sciences are never at war. . . . Permit me then as a public body with whom I am connected to solicit the exertion of your interest in the liberation of Lord Yarmouth". In 1805 Jenner addressed himself directly to Napoleon requesting that two of his friends, Mr. William Thomas Williams and Dr. John Wickham, both men of science and literature, might return to England. According to Baron, the well-known biographer of Jenner, it was either on this or a similar occasion that Napoleon exclaimed: "Jenner! Ah, we can refuse nothing to this man." Jenner was also successful in obtaining the release of Sir George Sinclair, who had been arrested as a spy at Göttingen. Besides helping to liberate Englishmen detained on the Continent, Jenner issued certificates stating that travellers abroad were known to him and were undertaking a voyage in pursuit of science or health or other affairs entirely unconnected with the war, and were in his opinion entitled to protection and freedom.

British School of Archæology at Athens, 1935-36

Although the Annual of the British School at Athens no longer provides a general view of the activities of the School and its students—information which now must be sought in a separate publication—its contents continue to record the more important operations of its members. The volume for 1935–36 (London: Macmillan and Co., Ltd., 1939. 42*s*. net), however, opens with an account, very fully illustrated, by Dr. Alex. Philadelphus, director of the National Museum of Athens, of the Anavysos Kouros, a remarkable example of archaic art, in fact "one of the most perfect and almost the last link in the long chain of Apollos or kouroi that have come down to us", probably dating at about 530 B.C. This statue, which was recovered in fragments from an antique dealer in Paris, had been smuggled out of Greece by sea a few years ago from Anavysos, near Laurium. Of the remainder of the contents of the volume the greater part is given up to the excavation of the cave of Trapeza on the plain of Lasithi in eastern Crete. This cave was first discovered by Sir Arthur Evans in 1896, who refers to it as containing objects mainly of the Hellenistic period, but also a faience figure of Bes and fragments of gold leaf, which afterwards found a parallel in the Early Minoan jewellery at Mokhlos. Apart from mention by Taramelli and Bosanquet, it received no attention from archæologists until 1935, when it was visited by members of the School. In 1936, between May 4 and 19, it was excavated by Miss Money-Coutts, Mr. and Mrs. J. D. S. Pendlebury and others. Judging from the finds, the contents of the cave originally must have been rich. Although metal was comparatively rare, gold, silver, bronze (or copper), and lead were all represented. The deposits in the cave, however, had been much disturbed by treasure hunters, and in one spot only were they intact. It has, therefore, been possible to study the pottery found for the most part on stylistic evidence only, and to reconstruct the history of the cave accordingly. It would appear to have been occupied as a habitation site in Late Neolithic, and to have been used for communal interment from Early Minoan II until the end of Early Minoan III.

The Cyclotron and Biological and Medical Research

Dr. G. E. Harrison, lecturer in physics, in the University of Birmingham, has been elected to a Rockefeller Foundation fellowship in natural science which will enable him to spend a year at Berkeley University, California, studying under Profs. J. H. and E. O. Lawrence. The object of the visit is to acquire first-hand knowledge of the application of neutrons to biological and therapeutic research, in which the Profs. Lawrence have opened up a new field the exploration of which seems likely to be of first-rate importance in the treatment of disease. Berkeley University, where Prof. Lawrence constructed his cyclotron and has developed his own technique, is unique in facilities for the production of neutrons and artificial radioactive substances. When the large cyclotron which Prof. Oliphant is building for research in nuclear physics in the Physics Department of the University of Birmingham is completed, this University, in which the Physics Department and new Medical School are in close proximity, will be in an exceptionally favourable position for the promotion of the therapeutic and physiological investigations which Prof. Lawrence at Berkeley and Prof. Hevesy at Copenhagen have so strikingly originated. It is hoped that on his return from California, Dr. Harrison will organize and direct research in these subjects in the University of Birmingham.

The Ontario Research Foundation

THE report of the Ontario Research Foundation for the year 1938 (Sessions Paper, No. 48, 1939. Pp. 36. Toronto: King's Printer, 1939) refers to the extension of the soil survey of the central part of Southern Ontario eastward to the Quebec border. The Department of Agriculture has also determined the general relations between the performance of certain varieties of apple, and climatic and soil conditions in the apple-growing sections of the Province. The Department of Pathology and Bacteriology has continued its studies of bovine mastitis. Attention has been focused on the prevention of human infection by pasteurization of milk, and experimental work was continued during the year on *Brucella Abortus*. Studies relating to the sheep nose fly were continued during the year as well as on the parasites of game and fish. The Textiles Department has been responsible for investigations on causes of fabric fraying and the quantitative and consistent measurement of this tendency. They have also been responsible for testing work on the fastness to light of dyestuffs used in the Canadian textile industry, and have commenced a study of the fundamental and physical characteristics of single silk fibres. The testing work and control work of the department, particularly in connexion with rayon merchandise, have also increased. The facilities of the Department of Engineering and Metallurgy for the investigation of products associated with air-conditioning have been extended, and were put to considerable use in the year. A study of the resistance of metals and alloys to abrasion and wear has developed to a stage which permitted a new programme of work to be prepared, and results of tests on suitable metals have been collated.

THE Department of Chemistry in its investigation of paint failures in the Paint and Varnish Laboratory has continued to yield information essential to understand the problem of protective finishes, and a fundamental investigation of the processing of drying oils is in progress. Other work on a low cost plastic moulding powder prepared from wood meal has overcome the difficulties due to the absence of some properties which are essential to commercial success, and a low cost powder is now available which can be moulded commercially. Interpolymerization of styrene and other organic chemicals has been studied in the cellulose and plastics laboratory and a new series of interpolymers developed which are notable in their resistance to swelling in commercial solvents. During the year an Analytical Laboratory was established to serve as a central laboratory in the Foundation for analytical problems. The Paper, Printing and Adhesives Laboratory has worked mainly on packaging and adhesive problems due to difficulties through odours and moisture. In the Department of Biochemistry work on the production of lactic acid and other chemicals by the action of micro-organisms has been conducted, as well as pilot scale tannery operations to improve the vegetable chrome process for the manufacture of sole and belting leather which was developed in 1937, and in addition to improving the colour of the leather it is hoped to improve still further its durability under normal wearing conditions. Attention is also being given to the development of spue on finished leather, and a complete report on the technology and economics of pectin production has been prepared for one of the large apple growers of the Province.

"Nomenclator Zoologicus"

WE have received a sample part of the "Nomenclator Zoologicus", edited by Dr. S. A. Neave, of which the first volume is about to be published by the Zoological Society. The work, which will be completed in four volumes, aims at giving "as complete a record as possible of the bibliographical origins of the name of every genus and subgenus in zoology published since 1758, the date of the tenth edition of Linnæus' 'Systema Naturæ', up to the end of the year 1935". Up to 1850, not only the generic but also the specific names are indexed in Sherborn's monumental "Index Animalium". Since that date, however, the scale of zoological publication has increased so vastly that a continuation of "Sherborn" would be a task of overwhelming magnitude. Even in the all-important matter of generic names the systematist has been compelled to spend much time and labour in tracing their origin and in trying to avoid re-inventing old names for new genera. The "Nomenclator Animalium generum et subgenerum" published by the Prussian Academy of Sciences, begun in 1926, was designed to remedy this state of affairs, but it has been making its appearance in so leisurely a fashion that, although already thirteen years out of date, it is not yet completed. Dr. Neave, who has had the assistance of the specialists on the staff of the British Museum (Natural History), as well as of many other zoologists in Great Britain and abroad, hopes to complete publication by the end of 1940. Apart from cross-references and variations in spelling, he and his collaborators have collected about 192,000 generic names, of which at least 5,000 have escaped inclusion in former nomenclators and in the "Zoological Record". No doubt many omissions remain to be discovered, and zoologists are asked to send a note of any they may find so that they may be included in a supplementary list at the end of the last volume.

Forestry in South Africa

WE welcome the issue of the first number of a new forestry publication appearing in the *Journal of the South African Association* (No. 1, Oct. 1938, Pretoria, published by the Association, April and

October, 1938). The number opens with a fitting memorial to the late Mr. J. P. Bekker, administrator of the Transvaal, who was keenly interested in forestry, and one of the earliest advocates of extensive afforestation in the Transvaal. The most important article, which alone would make this number of the *Journal* of high value, is the "Historical Sketch of the Development of Forestry in South Africa" by N. L. King, chief management officer, Division of Forestry. To those interested in forestry progress in the Dominion, a perusal of the paper is recommended. There is a strange omission, however. The author, although he alludes to the early settlers who landed at the Cape in 1652, makes no reference to the fact that they imported in the seventeenth century the oaks and poplars.

The new journal contains several articles of technical interest to South Africa. In connexion with the important questions of erosion and desiccation in Africa, now receiving serious attention, the brief note, accompanied by some startling photographs, by Colonel Deneys Reitz, M.P., on "The Forests of Northern Zululand" is arresting. Colonel Reitz depicts areas of forest which he knew fifteen years ago with the present state of affairs. "In those days this area consisted of open savannah plains plentifully interspersed with park-like groves of timber. In addition there was the extensive Mongosi Forest and several other valuable forests at Mpatu, Mocsi and elsewhere. . . ." The author shows that the greater part of the groves and the forest areas have now disappeared to make 'gardens', that is, cultivation. Among other articles of interest is one by F. S. Laughton on the "Raising of Transplants of Indigenous Tree Species for Open-Rooted Planting" and a paper by S. P. Sherry entitled "The Rate of Growth and Health of the Southern Pines in the Midland Conservancy".

Control of the Chrysanthemum Midge

A law case of interest to chrysanthemum growers was heard at Littlehampton on July 3 when a nurseryman was prosecuted by the Ministry of Agriculture and Fisheries for failure to comply with a notice requiring him to take certain measures for the extirpation of the chrysanthemum midge from his premises. The chrysanthemum midge is a serious pest of greenhouse chrysanthemums in North America, and during the past two years it has been found to exist in a few nurseries in England. The control measures to be adopted, if the pest became established in Great Britain, would add greatly to the cost of growing chrysanthemums. For this reason drastic measures are enforced with the view of eradicating the pest where it has been found and preventing its spread to other nurseries. It is in the interests of all that outbreaks should be speedily discovered and notified to the Ministry. Growers of chrysanthemums are advised to watch their plants carefully and to send to the Ministry specimens of plants attacked by any insect with which they are unfamiliar. An illustrated leaflet (Advisory Leaflet No. 286), which gives a full description of the chrysanthemum midge and its habits, may be obtained on application to the Ministry at 10 Whitehall Place, London, S.W.1.

Modification of the Steiner Composting Process

The present-day shortage of organic fertilizers has naturally led to special attention being paid to methods of composting. Recently a claim has been put forward by Miss Maye Bruce, of Sapperton, Gloucestershire, that she has developed a modification of the Steiner process which results in a more rapid decomposition of the waste material and a more valuable product from the fertilizing point of view (*J. Min. Agric.*, 46, No. 3, 295; 1939). A layer of charcoal is spread over a foundation of rubble, and a wall, about 4 ft. high, of wood or brick built round it. Garden refuse of a non-woody nature is then thrown on, particular value being attached to stinging nettles. Unslaked lime is sprinkled when the first and third foot levels are reached and animal manure, if available, is applied at the second foot level. The unique part of the method, however, lies in the recommendation that the further addition of six herbal essences, namely, nettle, yarrow, camomile, valerian, dandelion and oakbark, together with pure run honey, in a solution of 1 part in 10,000 adds greatly to the value of the compost. The heap should be covered with about 6 in. of soil and protected from rain, and after six weeks in summer, or twelve in winter, the refuse becomes a rich, friable and sweet smelling heap of compost. Further information as to how to make and use these essences can be obtained from Miss Bruce, who is also willing to forward them at a nominal charge to cover packing and postage.

Electric Heating of Domestic Hot Water Supply

The important paper on "The Application of Electric Heating to Domestic Hot-water Supply Systems" read to the Institution of Electrical Engineers and to seven local centres is published in the *Journal* of the Institution of July. In the discussion, Mr. A. E. McKenzie, engineer to the Wimbledon Corporation, said that in the three towns supplied by his undertaking, there are 38,000 consumers taking electricity and 17,633 electric water heaters. This gives one water heater for every 2·15 houses, or approximately 46 per cent saturation. In addition, there are a large number of publicly owned heaters. In Wimbledon, all self-contained water heaters are cleaned out once in two years, and four improvers are employed continuously on this work. All the heaters in a street are cleaned at the same time, thereby cutting maintenance costs down to a minimum. Taken over a period of years, the cost of cleaning such heaters, both large and small, averages 1*d*. per month. As the numbers increase, it is hoped that this cost will soon fall. The problem of 'scaling' is more serious with the small heaters than with the big ones. Most of the scale is deposited at the top of the outlet pipe and at the anti-dripping device which is immediately over it. There is no necessity to remove any of the electrical connexions. This enables the heater to be renovated less than half the time and at less than half the t formerly necessary. A strong case can be made for the claim that the electric water heater is re trustworthy than any other type. At Wimbledon re are 5,000 of the self-cleaning type installed and re has not been a failure. Serious accidents due electric water heaters are practically unknown. ring the severe weather last winter, only twelve ters were put out of action, all of which functioned mediately the ice was melted in the supply es.

Californian School of Education

To have directed one of the foremost schools of ucation in the United States from 1898 until 33, to have presided during those thirty-five years er the training of nearly three thousand of the duates whom it has sent out to all parts of the ited States and beyond, many of them to occupy ategic positions in the educational world as prosors, research workers and school and college cutives, and to crown this life's work by presenting with a new 500,000-dollar building paid for out of proceeds, judiciously invested, of spare-time nings during all those years—to few is it given in ir declining years to look back on so satisfying achievement. It is commemorated in a pamphlet ently issued by Stanford University in connexion h the opening of the University School of Educan Building—the gift of Dean (emeritus) Cubberley d his wife. A noteworthy feature of the School ce the Great War is the importance of the summer arter, during which most of the students are ool executives or teachers, contacts between om and the School faculty have proved highly mulating. The summer is indeed regarded as the st important quarter of the university year for truction in the field of education. The delightful mmer climate of the Santa Clara Valley is one of School's most valuable assets. An article by the sent Dean emphasizes the conception that prosional study in education should have a foundation scholarship in the social studies and in psychology d human biology. "The school has been one of most static of the social institutions. . . . iversity schools of education have responsibility developing new conceptions and techniques of ucation which are more adequate for modern iety," so that the school system may develop in people "the vision, the creativeness, the initiative, critical-mindedness, the understanding, and the cipline which will . . . give expression to the nocratic social ideals."

useums of Norwich

THE Museums Committee of the City Council has t issued a report covering ten years' development 29–1938) in the museums of Norwich. It has n a period of noteworthy progress, partly on ount of the value and number of gifts and bequests de to the museums, but mainly on account of the vances made in museum arrangement and appeal. e exterior and amenities of the Castle Museum, with its Norman keep and magnificent Norman doorway, have been attended to following the advice of H.M. Office of Works, and great reorganization has taken place in the collections exhibited within. It was a wise move to reduce the excessive space formerly given to exhibits, often reduplicated, of British birds, in order to allow a more balanced representation of the animal kingdom; and the creation of dioramas of representative stretches of Norfolk scenery with the appropriate flora and fauna adds greatly to the instructiveness and attraction of the collections. In the Art Galleries the valuable paintings of the Cotman period are undergoing restoration where this has been found to be desirable, and a scheme of redecoration has been followed by successful experiments in the rearranging of the pictures themselves. In other directions the museums show that they are keeping in pace with modern developments, and none of these is more gratifying than the success of the collaboration with the Education Authority for regular visits of school classes to the various museums.

Public Health Statistics of India

THE annual report of the Public Health Commissioner to the Government of India for 1936, in two volumes, has recently been issued (Government of India Press, New Delhi, 1938. Vol. 1, Rs. 2, or 3*s*. 6*d*.; vol. 2, Rs. 1, annas 10, or 2*s*. 9*d*). The state of the public health of the civil population in British India is surveyed in vol. 1. The mid-year estimated population was 281,866,639—an increase of 3½ millions over 1935. The death-rate was 23, and the birth-rate 35, per 1,000, and the infantile death-rate per 1,000 live births was 162, compared with 164 for 1935. The deaths from cholera numbered 160,000, some 57,000 less than in the previous year, and those from plague were only 13,000, less than half the figure for 1935; but the deaths from smallpox numbered 104,805 or 14,000 more than in the previous year. Deaths recorded under 'fevers' decreased by 4 per cent, but small percentage increases were recorded in respiratory diseases and the diarrhœa and dysentery group. Deaths recorded from hydrophobia numbered no fewer than 2,470. In vol. 2, the general health statistics of the British Army in India and of the Indian Army are considered. The general health of the troops seems to have been well maintained, though admissions to hospital among the British were a little higher than in the previous year. The incidence of the enteric group of fevers is the lowest ever recorded, and is particularly striking among the Indian troops. There has been no corresponding reduction among the civil population, but rather an increase. The decrease of enteric fevers in the Army must, it would seem, be ascribed to more general and better anti-typhoid vaccination, and to a more careful search for, and elimination of, carriers.

Child Welfare Organization

THE League of Nations has published the annual report on child welfare prepared by the Child Welfare Information Centre (London: George Allen and

Unwin, Ltd., 4*s*.). The report gives *inter alia* a general account of the measures adopted in China, with a summary of the work being done in the province of Kwang-si, the most advanced province as regards the organization of social services. Information on the United States and the United Kingdom is very complete. The report should prove useful to all who are interested in the social development of various countries and the measures adopted to protect the mother and child.

Safeguarding Water Supplies

A MEMORANDUM setting out the precautions necessary in the administration of a water supply undertaking in order to maintain the wholesomeness of the supply has been sent by the Minister of Health to all water undertakings ("Memorandum on the Safeguards to be Adopted in Day to Day Administration of Water Undertakings". Mem. 221. H.M. Stationery Office). These precautions are those that have long been recognized as good practice in water administration, and include care in the selection of workmen so as to exclude possible infection through carriers, particularly during repair work, inspection of gathering grounds, frequent and regular analyses of the water supplied, and the use of special treatment such as chlorination.

Research in the London Hospital

The Publications Committee, with Prof. Bedson as its secretary, has issued a volume of "Researches Published from the Wards and Laboratories of the London Hospital during 1938" (London: H. K. Lewis and Co., Ltd.; 7*s*. 6*d*. net). It includes thirty-seven papers dealing with a wide range of subjects—physiological, pathological, biochemical and clinical—which are evidence, if that were needed, of the active studies upon problems of health and of disease that are being pursued at this great medical school and hospital.

Studentships and Fellowships in Medical Research

The Medical Research Council invites applications for a fourth series of studentships and fellowships intended to encourage young British medical graduates towards becoming investigators in those branches of medical science which are concerned directly with disease as it occurs in human beings. Post-graduate studentships are offered for medical graduates who have already held house appointments and are strongly inclined to a career in clinical science or experimental pathology. Each selected student will receive a stipend at the rate of £200 per annum, during a period not exceeding twelve months, for personal maintenance while undertaking approved courses of study in Great Britain such as may be regarded as best calculated to advance the student's training in methods of research. Research fellowships are also offered for candidates of similar qualifications who have already had some experience in the use of research methods. Each fellowship will be tenable for one year at the ordinary value of £250 per annum, and will be renewable in approved instan
at the rate of £300 per annum for a second ye
These fellowships are intended as probationa
appointments for research in clinical science
experimental pathology under suitable direction
Great Britain. Research expenses may be provid
in addition to stipend. Further information can
obtained from the Secretary, Medical Resea
Council, 38 Old Queen Street, London, S.W.1.

Announcements

Prof. A. J. Clark, professor of materia medica
the University of Edinburgh, and Prof. T. R. Ellio
emeritus professor of medicine in the University
London and consulting physician to Univers
College Hospital, have been appointed members
the Medical Research Council, in succession to Pr
H. S. Raper and Prof. J. A. Ryle, who retire
rotation on September 30.

Dr. Dean Burk, formerly chemist in the Bure
of Chemistry and Soils, U.S. Department of Ag
culture, has been appointed senior chemist in
newly established National Cancer Institute, U
Public Health Service, and associate professor
biochemistry at Cornell University Medical Coll
in New York City, where a study on tissue me
bolism fundamental to cancer will be carried
under the auspices of a grant made by the Natio
Advisory Cancer Council to the Department
Biochemistry headed by Prof. Vincent du Vignea
Collaborating in the investigations will be Dr. Fr
Lipmann, formerly research associate of Prof. O
Meyerhof and of Dr. P. A. Levene of the Rockefel
Institute, and lately with Dr. Albert Fischer at
Carlsbergfondets Biologiske Institut, Copenhagen.

Dr. Friedrich Karl Kleine, honorary profes
of hygiene in the University of Berlin and an exp
on tropical diseases, has recently been awarded
Shield of Nobility of the Reich by the Germ
Chancellor.

Prof. Ludwig Jost, professor of botany in
University of Heidelberg, has been awarded
Charles R. Barnes honorary life membership of
American Society of Plant Physiology.

The Autumn Meeting of the Iron and St
Institute will be held in Cardiff during Septem
12–15. Further information can be obtained fr
the Secretary, Iron and Steel Institute, 4 Grosve
Gardens, London, S.W.1.

The John Burroughs Association desires to get
touch with organizations throughout the world wh
have been formed in honour of John Burroughs,
American poet and naturalist, with the view of c
lecting opinions concerning an annual publicati
containing reports of such organizations and artic
on Burroughs. Communications should be addres
to the president of the Association, Dr. Clyde Fish
American Museum of Natural History, 77th Str
and Central Park West, New York City.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 291.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

eavy Cosmic Ray Particles at Jungfraujoch and Sea-Level

THE heavy ionising particles in the cosmic rays are rare that it seems unlikely that much information be obtained from experiments with cloud umbers. The only method at present available ich can yield quantitative results is the method of ect photography, which has been used recently several investigators mainly for investigating the clear disintegrations which the cosmic rays pro- ce[1,2]. On a plate which has been exposed for a ficiently long time is observed, in addition to a at wealth of phenomena associated with dis- egration effects, a large number of single tracks bably due to protons or slow mesotrons.

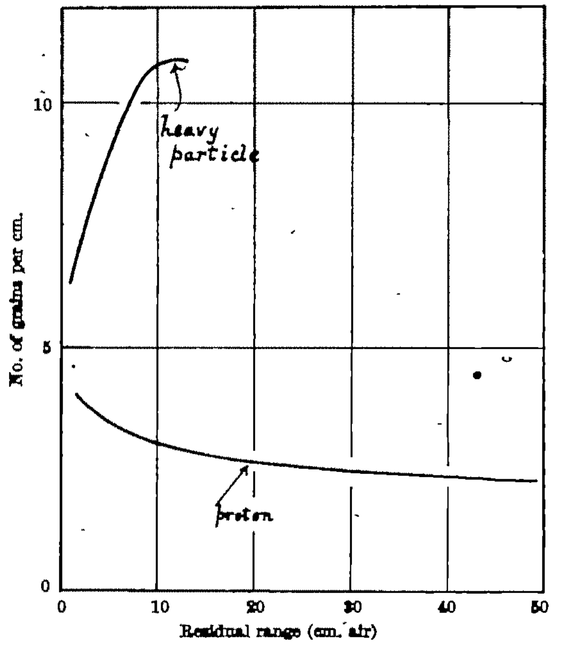
n approaching the problem of elucidating the ious processes taking place, the first question ich presents itself is that of the nature of the mary radiation responsible for the heavy tracks, l we have therefore made absorption measure- nts in lead and air. A set of Ilford half-tone plates ulsion 70 μ thick and sensitive to α-particles and otons), covered with different thicknesses of lead, ve been exposed to cosmic rays on the Jungfraujoch l in Bristol for a period of 230 days. We divide observed tracks into two classes according to ir length (that is, the length of the part of the ck appearing in the emulsion): (i) tracks less than cm. air equivalent and (ii) tracks greater than cm. air. A large fraction of (i) is due to radio- ive contamination, whereas all the tracks (ii) are cosmic ray origin. The results are given in the lowing table:

	No. of tracks greater than 10 cm. air per mm.^{2}	No. of tracks less than 10 cm. air per mm.^{2}
ungfraujoch, no lead	6·2 ± 1·0	20 ± 1·4
5 cm. „	8·4 ± 1·0	27 ± 2·0
18 cm. „	4·5 ± 1·0	16 ± 1·5
ristol, no lead	0·6 ± 0·2	11 ± 1·5
18 cm. „	0·25 ± 0·2	14 ± 2·0

t will be seen that radiation primarily responsible the long tracks suffers practically no absorption lead but is strongly absorbed in air. The short cks also indicate that the primary radiation giving to them is strongly absorbed in air but not in d. (Probably most of the short tracks on the stol plates are of radioactive origin, and we must ect an equal number of this origin in the Jungfrau tes.)

he results show that the *long tracks are neither duced by the electron nor by the mesotron com- ent*. Electrons would be strongly absorbed in d, whereas the mesotron intensity increases only a factor 1·7 between Bristol and Jungfraujoch. *heavy tracks are therefore produced by a third ponent*. It seems likely that this third component consists of *neutrons*. Further support for this view is given by the experiments of Schopper[3]. Experiments with paraffin as absorber are in progress.

The grain spacing of the tracks is in agreement with that of artificially produced protons. Most of the long tracks are probably protons; but it cannot be excluded that some of the shorter tracks due to cosmic rays are also α-particles, since on the half-tone plates there is little difference between the grain spacing of α-particles and protons. The distribution of tracks was found to be more or less isotropic. The plates were placed in a horizontal position, but no appreciable preponderance of vertical tracks was observed.



We have also observed numerous disintegration stars which will be the subject of a later investigation. Here we only wish to mention one particular case, similar to a heavy particle in a disintegration star observed by Schopper and Schopper[3], which is of interest in connexion with the question of nuclear fission. The star in question has five tracks: four of them are comparatively short (5–11 cm. air) proton or α-ray tracks. The fifth track is 14 cm. long and has an average grain density of about *three times* that of α-rays of 8 cm. range. Considering that there is very little difference between the grain density produced by protons and α-particles of the same range, we must ascribe this track to a heavy particle with a *very high effective charge*. Moreover, the grain density does not increase steadily towards the end of the range, as is the case for α-particles, but has a maximum at the beginning of its path and then decreases slowly, until at the end of its range it approaches that of an α-particle (see accompanying diagram). This effect is presumably due to capture of extra nuclear electrons.

We do not think it very likely that this track represents the mere recoil from the original cosmic ray particle. The recoil tracks in even very energetic disintegrations are very short, and besides, there is no reason why the recoil nucleus should have such a high effective charge. In all probability we are dealing here with a heavy, highly charged splinter, released by a highly excited heavy nucleus, a process which bears some similarity to the fission of the uranium nucleus.

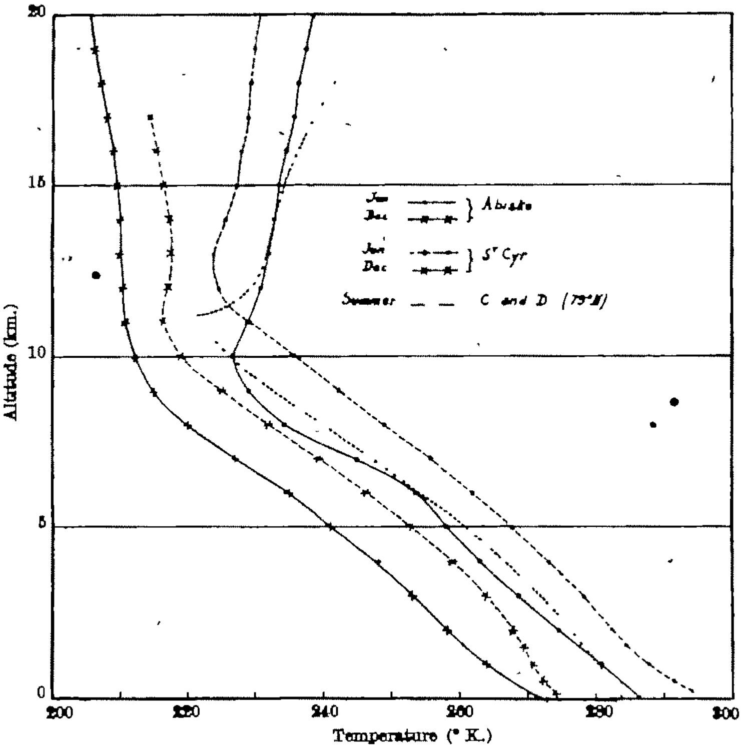
Temperature of the Stratosphere in High Latitudes

We recently directed attention[1] on the variation of the 'mean temperature' of atmospheric ozone, which appeared from the observations made by Barbier, Chalonge and E. Vassy at Abisko (Swedish Lapland, lat. 68° 20′ N.) between December 27, 1934 and March 6, 1935. From the end of December until the beginning of March, the temperature gradually increased by about 70° C. This great variation may seem surprising, as the stratosphere is known to have a rather constant temperature; but it should first be noticed that the mean temperature of atmospheric ozone involves altitudes not accessible to sounding balloons; a next, that the stratosphere has been investiga chiefly in low and middle latitudes.



Rolf[2], however, at Abisko between 1921 and 19 carried out a long series of measurements show that above the tropopause the temperature decrea slightly in January, while in June it increases i regular manner, as may be seen in the accompany graph.

For the sake of comparison, there are represented the same graph similar curves deduced from ra soundings made at Saint-Cyr (lat. 48° 47′ N.)[3]. cently published observations, made by Carmich and Dymond[4], suggest that this increase of tempe ture in summer is yet more marked (25° C.) in hig latitudes (about lat. 79° N.).

Thus, direct measurements point to an ann change in the temperature of the stratosphere, the higher the altitude, the greater the differe between the summer and winter temperatures. arctic countries, this change is much greater than lower latitudes. This was also noticed by Penndo

The measurements of the mean temperature atmospheric ozone, as they reach much higher regi in the stratosphere, are an extrapolation of balloon measurements, and strengthen the opin that this annual variation increases with altitu Thus the earth's atmosphere offers two arctic zo by turns very cold in winter and very warm summer.

Solar radiation would be resp sible for these variations. For is easy to estimate, for a given d the time when the higher layers of atmosphere are illuminated; tak also into account the obliquity of sun's rays, a strong correlation found between the illumination the mean temperature of ozone.

In addition, Gowan's calculatio though they deal with lower latitu (50° N.), show a large difference in higher layers of the stratosphere tween the actual temperature and temperature when the atmosphere plunged in darkness during a suffici time for equilibrium to be attain which is nearly the case in p night.

One of the consequences of the lated phenomenon is a possible expla tion, owing to the dependence of velocity constant of thermal dec position on temperature, of the decr ing ozone thicknesses at Abisko wh are shown by Dobson's curve[7].

terpretation of the Red-Shifts of the Light from Extra-Galactic Nebulæ

In his most recent contribution on this subject[1] ubble mentions a red-shift of + 0·231 A. This rresponds to a velocity of recession of approxiately 43,000 miles per second, nearly a quarter of e velocity of light ! The conviction grows upon one at these fantastic velocities are not real.

Alternative interpretations of the red-shift have en proposed, but have failed to provide an accept-le explanation. No one has taken account of the ot that a list of the available determinations of the locity of light shows a steady decrease of velocity th time, following a linear law, $c = 299{,}900 -$ 855 T, for the epoch 1900[2] (see Table 1).

TABLE 1.

T	c
1902·4	299,901 ± 84 km./sec.
1924·6	299,802 ± 30
1926·0	299,796 ± 4
1928·5	299,778 ± 20
1932·1	299,774 ± 11
1937·7	299,764 ± 15
1938·5	299,761 ± ?

This may be due to a 'fatigue' phenomenon : there e in Nature no inexhaustible stores of energy, no amples of perpetual motion. There are tremendous res of energy and the ensuing motion may continue thout perceptible alteration for periods almost yond reckoning, but neither lasts indefinitely. The ergy of a photon is not considerable and an exmation of the slowing-down may be sought in a crease of frequency as the light journeys through ace. It may be sought in the fact that the velocity propagation of a vibration depends on the physical operties (gravitational, electrical, magnetic, atomic, ermal and probably others) of the space through nich it is propagated, and that these properties are adually altering. Whatever its explanation, the wing-down is an observed fact.

Besides this, a satisfactory interpretation of the d-shifts must conform to the following further served facts :

(1) Strömberg, by measuring the aberration of ht from nebulæ of the Ursa Major I cluster, has own that the velocity of the light from this cluster the same as that of light from laboratory sources[3]. ght from all sources, near and far, reach therefore e eye with the same velocity, c.

(2) Planck's constant h is constant, for Adams d Humason[3] have shown that the relation $E\lambda = ch$ holds good for sources of light near and far, by mparing a grating and a prism spectrogram of the ission spectrum of the nucleus of *N.G.C.* 4151.

(3) The wave-length is constant during the light's urney : this assumption is accepted as correct when asuring radial velocities.

(4) The frequency n of a newly generated photon energy E is the same for all sources of light near d far, since (1) may be written $E = hn$, and it is admitted that the energy of a photon generated by an atom of the same element under the same conditions is the same in all sources near and far. For example, the energy of the photon giving the K line of Ca+ has the same energy whether generated in a remote nebula or on the earth.

It follows from the above that light leaves a remote nebula with a velocity $c_e > c$, and a wave-length λ_e given by the relation $c_e = n\lambda_e$ (2). During the light's journey, both c_e and n decrease until, when the light reaches the earth, they have become c and n' respectively, with $c = n'\lambda_e$ (3) and n' is less than n. Since $c_e > c$, from (2), $\lambda_e > \lambda$, the corresponding wave-length of light from laboratory sources, and $\lambda_e = \lambda + d\lambda$, which is the observed red-shift.

In Table 2, m_c is the luminosity of the fifth brightest nebula in each cluster (the clusters are so similar that this gives a precise measurement of distance) and $d\lambda/\lambda$ is the observed red-shift[1]. R is the distance in light years, from the relation $\log r = 0{\cdot}2\, m_c + 4{\cdot}803$; λ_e is the initial wave-length of the K line of Ca+, calculated from the red-shift, taking its earth value as $\lambda = 3933$ A.—it is the wave-length at both ends of the light's journey ; n' is the frequency of the light from the nebula when it reaches the earth, and c_e is the initial velocity of the light. The nebulæ are in order of increasing distances. The data relating to Ursa Major II are inconclusive : they have been derived from a single spectrogram of a single nebula only.

TABLE 2.

Cluster	m_c	$d\lambda/\lambda$	r light-years	λ_e of K line of Ca+	n'	c_e
—	—	—	—	($\lambda = 3933$ A.)	($n = 762{\cdot}2 \times 10^{12}$)	($c = 299774$ km./sec.)
Virgo	10·40	0·0041 A.	8×10^6	3949 A.	$759{\cdot}1 \times 10^{12}$	300990
Pegasus	12·88	0·0127	24	3983	752·6	303585
Perseus	13·48	0·0174	31·6	4001	749·1	305080
Coma	14·23	0·0245	44·6	4029	744·0	307090
U. Ma. I	16·12	0·0517	106·4	4137	724·6	315320
Leo	16·33	0·0653	117	4190	715·5	319360
Cor. Bor.	16·54	0·0707	129	4211	711·9	320960
(U. Ma. II	17·73	0·1403	223·4	4485	668·4	341850)
Boötes	17·89	0·1307	240·4	4447	674·1	338950

The slowing down of the frequency and of the velocity both follow linear laws : $n' (\times 10^{12}) = 762{\cdot}2 - 0{\cdot}4\, T$; and c_e(Km./sec.) $= 299774 - 173\, T$, where T is in millions of years.

Accordingly, 240 millions years ago, light travelled with a velocity approximately 13 per cent greater than now, and the wave-length of the K line of Ca+ was 4447 A.

Should the above be confirmed, our measurements of stellar radial velocities will require a correction depending on the distance.

Interrelation of Dissociation Energy and Inter-nuclear Distance for some Simple Di-Atoms in Ground States

HAVING recently suggested[1] that Dr_e^2 (D dissociation energy, r_e internuclear distance) is approximately constant for C—C linkages in solid carbon and in hydrocarbons, I find further that $x = Dr_e^2 n^{1/2}$

(n group number) tends to constancy, within experimental errors, for ground states of simple di-atoms of related type (for example, LiLi, NN and OO).

Using the relation $k_e r_e^6 = pD$ (k_e bond constant, p a constant product for di-atoms of related type[1]), it follows that $k_e r_e^6 n^{1/2} = px$. Fox and Martin[3] find $k_e r_e^6$ constant for C—C linkages: further examination shows that it also connects ground and excited states of the di-atom CC. In general, however, $k_e r_e^6$ seems more useful for correlating different states of a given di-atom, and this is suggested by the Morse-Clark function, which leads to $k_e r_e^6 n = py$, where $y = Dr_e^6 n$, for cases where the reduced mass does not vary greatly. This relation between k_e and r_e is essentially that already used with some success for hydrides and deuterides[4], and conforms with a suggestion made by Sutherland[5], to meet a well-known difficulty which appears in the Morse-Clark expression in the case of isotopic forms. The function y is closely constant in the KH period, where the reduced masses are nearly alike. For HH, HD and DD, x and y give equally concordant results.

Whilst x (or y) appear sensibly constant in appropriate periods, p is more susceptible to change in electron configuration: thus in ground states $p(\text{LiLi,KK}ss) = 9\cdot9$, $p(\text{OO,KK}pp) = 20\cdot9$, while $x = 30\cdot7$ volt A^{3} very nearly in both cases. Fox and Martin[3], in agreement with this, find $p = 20\cdot7$ for C—C linkages (KKpp type). However, for a given configuration in a given period of di-atoms, p varies with x (or y) in such a way that px (or py) is sensibly constant for excited as well as ground states, and may be equated to period constants of the type K_{σ}.

It is hoped that reliable and more general relations connecting D, k_e and r_e may emerge from this. The detailed results of calculation will be submitted for publication elsewhere.

I am indebted to Dr. J. J. Fox for much helpful discussion.

Differential Threshold for Compression Modulus

WE have recently described[1] experiments in which it was shown that individuals differed but slightly in their capacity to distinguish by touch small differences in viscosity of highly viscous true fluids, and that an 80 per cent level of correct judgments corresponds to a viscosity difference of about 30 per cent.

We have now carried out similar experiments with rubber cylinders in which the compression modulus varied slightly*, the subjects being asked, as in the viscosity experiment, to select the 'softer' of two samples. For the rubber cylinders there are significant differences between individuals (χ^2 method) and further, those of our subjects regularly engaged in routine testing are superior as a group. Less educated and younger subjects are also superior, but it has n been possible to distinguish the separate effects education and age.

Taking the results for all ten subjects togethe our data may be summarized as follows:

	Pairs differing in compression modulus b per cent (means)					
	1·47	2·74	5·66	9·50	10·50	12·
Per cent correct	35	49	72	81	85	9

Vanadiferous Nodules in Worcester Clay

THE presence of dark nodules in the red Permi marls of South Devon has been recorded[1]. The nodules, which range from pin points to masses many pounds in weight, attain their maximu development one mile west of Budleigh Salterto They are surrounded by aureoles of green clay, co tain some 14 per cent of vanadium (estimated as V$_2$C and are radioactive.

We have found analogous structures in the Keup marls of Gregory's Bank, Worcester. They a mostly very small and, *in section*, consist usually of black centre ranging from a pin point to 0·8 cı diameter, the larger ones with a greyish centre a surrounded by a disk of green clay 1–2 cm. in di meter, the perimeter of which is sharply defin against the general background of red clay. T largest nodule found weighed 8 gm. and was eg shaped. Strata of green clay also occur in the Ba and contain numerous small black inclusions.

The green aureole contains ferrous iron and, as spectrogram appears identical with that of t adjacent red clay, it seems reasonable to conclu that it has been formed from the latter by reducti or removal of the ferric iron; but it is not cle how this has been effected. The black and gr centres contain some 5·6 and 8·6 per cent spectively of vanadium (calculated as V$_2$O$_5$), wi traces of titanium; but no nickel could be detecte Any radioactivity must be extremely weak as photographic plate was not appreciably affect after one month of direct contact.

Co-operative Activation

A CONSIDERABLE number of examples of chemical reactions in organized condensed systems have been observed to occur with activation energies greater than those normally associated with the temperature range at which the reactions occur. These reactions are: (1) the denaturation of proteins, where activation energies of 50–150 k.cal. have been reported[1], (2) $CaCO_3.6H_2O \rightarrow CaCO_3 + 6H_2O$ [2], (3) $K_2SO_4.Cr_2(SO_4)_3 24H_2O \rightarrow K_2SO_4.Cr_2(SO_4)_3 12H_2O + 12H_2O$ [3] and (4) the production of detonation nuclei in solid explosives[4]. On the other hand, in many solid reactions there is no marked deviation from the Polanyi-Wigner equation, the rate in molecules per sq. cm. being given by $\nu.e^{-E/RT}.N$. Thus there is no very large deviation in the case of $Ag_2CO_3 \rightarrow Ag_2O + CO_2$ [5] or $CuSO_4 5H_2O \rightarrow CuSO_4 3H_2O + 2H_2O$ [6], and in exothermic solid reactions; the following figures bear out the same point.

	Temp. ° C.	Rates (mols./cm.² sec.)	
		Calc.	Exp.
Lead azide	270	$1 \cdot 2 \times 10^{13}$	$5 \cdot 3 \times 10^{13}$ [7]
Potassium azide	251	$2 \cdot 0 \times 10^{18}$	$1 \cdot 7 \times 10^{18}$ [8]
Nitrogen iodide	−19	$8 \cdot 5 \times 10^{14}$	$6 \cdot 6 \times 10^{14}$ [9]
Barium azide	115	$1 \cdot 8 \times 10^{17}$	$3 \cdot 1 \times 10^{16}$ [10]

In all these cases, the thermal decomposition is believed to be simple, the unit processes involving at the most the decomposition or the liberation of one or two molecules. For the decomposition of calcium carbonate hexahydrate, the discrepancy is 10^{23} and for chrome alum 10^{11} times. For the denaturation of proteins, the discrepancy is variable and sometimes much larger. It would, therefore, appear that the abnormal cases are those for which a large number of molecules or chemical bonds are involved in the unit reaction.

It is possible to explain the rapid rates of these abnormal processes as due to co-operative activation of a number of points n on the surface within a short time interval τ, the activation energy required at each point being E/n, where E is the measured activation energy. The magnification of the rate which is thereby attained depends, in a complex fashion, on the type of organization involved, on the number of points n which are activated, the number of points m out of which n are chosen, but is independent of the value of τ. For crystalline substances, $\tau = 1/\nu$, where ν is the frequency of lattice vibration $= 10^{13}$ sec.), but for colloidal substances in aqueous media τ may be so low as 10^{-8} sec.

If we consider the 100 face of a cubic lattice with four adjacent lattice points composing a co-operative group, then it can be shown that the rate of reaction is approximately 10^3 times greater than that for the process of activation of one point with the energy E. For five adjacent lattice points the magnification is approximately 10^4. If we increase either m or n appropriately, then the magnification can be increased to factors of the order of 10^{23}, which was found for the decomposition of calcium carbonate hexahydrate. In order to obtain magnifications of the correct order, it appears to be necessary to increase m, the number of lattice points out of which the n points are chosen. This would mean that the activated points are to be spread over a relatively wide area. Only in the case of detonation nuclei is there any evidence bearing on this point, and this indicates in lead azide and nitrogen iodide that the activated points are spread over an area relatively great compared with the ionic diameter.

For the denaturation of proteins, the process is depicted as the disruption of a small number of bonds within a small time interval of approximately 10^{-8} sec., out of a relatively large number distributed over the surface of the protein molecule, the activation energy for the breaking of each bond being E/n. If in this case m is 100 and n is 4, then the magnification will be 10^6 times. For the decomposition of hydrates, the co-operative activation is regarded as being spread over the surface of the crystal, activation occurring at key points in the lattice, the loss of water from these points which follows the activation being imagined to cause the breakdown of the lattice over a relatively wide area.

An alternative mechanism is one proposed by Eyring and Stearn[1], which ascribes the high rates of reaction to the occurrence of high entropy change on passing from the reactant to the activated complex. On the basis of this hypothesis, in the case of changes in the solid state, an abnormally high energy of activation should be found in those cases where there is a high degree of disorder produced during the reaction, that is, when there is an amorphous product, and a more normal value when the product was crystalline. There is, however, at the present time but little evidence bearing on this aspect of the matter.

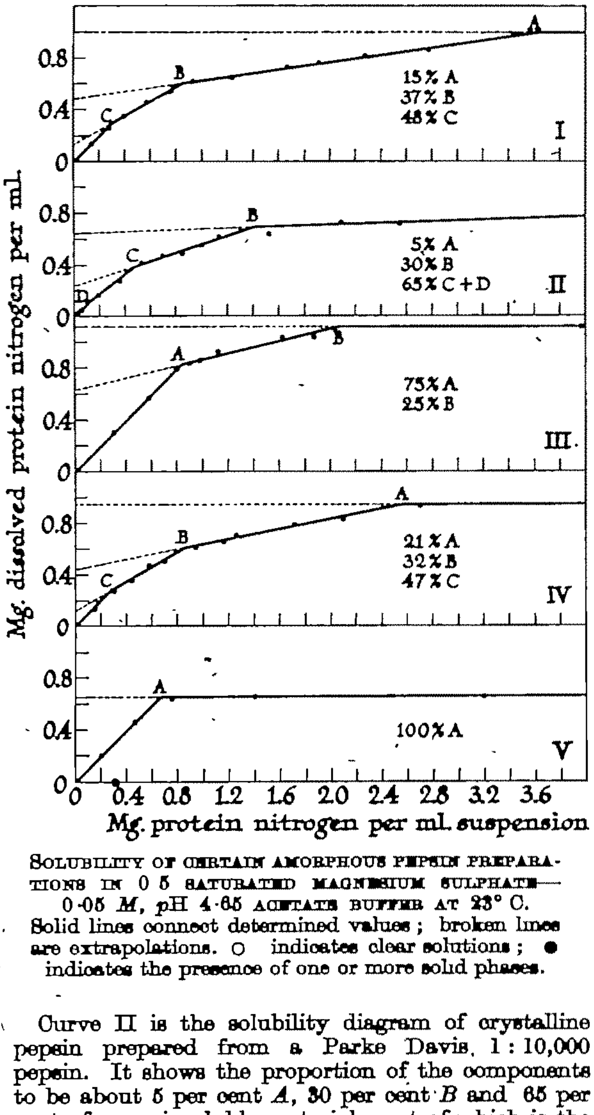
Existence of Several Active Components in Crude Pepsin Preparations

THE original solubility measurements on crystalline swine pepsin led to the conclusion that the crystals consisted of a single pure protein or several closely related proteins[1]. Since that time, it has become apparent in this and other laboratories[2,3] that pepsins prepared from the various commercial products or from pepsinogen differ in solubility, specific proteolytic activity and stability. Solubility measurements have now been made on various partially purified pepsin preparations in order to determine the cause of these variations.

The results show quite clearly that commercial preparations contain more than one protein possessing peptic activity and that the differences between the various preparations are due to differences in the proportion of the components present. Curve I shows the solubility diagram of the total protein fraction from a commercial 1 : 10,000 Cudahy pepsin preparation. When analysed, as described by Kunitz and Northrop[4], this curve indicates that the preparation is a mixture containing 15 per cent of component *A*, having a solubility of about 0·6 mgm. protein nitrogen per ml. in the solvent used; 32 per cent of *B* having a solubility close to 0·35 mgm. protein nitrogen per ml., and at least one other component, *C*, having a solubility of about 0·15 mgm. protein nitrogen per ml. The average specific activity[4] of this Cudahy preparation was $0\cdot26\ [\text{P.U.}]^{\text{Hb}}_{\text{mgm. P.N.}}$. The experimental methods are not sufficiently precise to allow one to draw positive conclusions with regard to the shape of the curves for the less soluble components.



SOLUBILITY OF CERTAIN AMORPHOUS PEPSIN PREPARATIONS IN 0·5 SATURATED MAGNESIUM SULPHATE—0·05 *M*, *p*H 4·65 ACETATE BUFFER AT 23° C. Solid lines connect determined values; broken lines are extrapolations. ○ indicates clear solutions; ● indicates the presence of one or more solid phases.

Curve II is the solubility diagram of crystalline pepsin prepared from a Parke Davis, 1 : 10,000 pepsin. It shows the proportion of the components to be about 5 per cent *A*, 30 per cent *B* and 65 per cent of more insoluble material, part of which is the *C* component having a solubility of about 0·15 mgm. protein nitrogen per ml., the remainder being designated as *D*. The average specific activity of the preparation was $0\cdot23\ [\text{P.U.}]^{\text{Hb}}_{\text{mgm. P.N.}}$.

Curve III is the diagram of pepsin prepared from pepsinogen by allowing a solution of pepsinogen to stand 18 hours at *p*H 3·6 and 5° C. Under these conditions, a precipitate forms which was discarded. The soluble fraction contains about 75 per cent *A* which therefore precipitates first in spite of its higher solubility, and 25 per cent of other components, most of which is *B*. The specific activity of this preparation was $0\cdot34\ [\text{P.U.}]^{\text{Hb}}_{\text{mgm. P.N.}}$.

If these analyses are correct, then a mixture of o part of pepsin from pepsinogen (Curve III) and thr parts of Parke Davis (Curve II) should contain 22 p cent *A* and 30 per cent *B*, and the average specif activity should be 0·26. The solubility curve of th mixture should be very similar to Curve I. Curve I shows the diagram for such a mixture. The cur indicates 21 per cent *A* and 32 per cent *B*, and th determined specific activity was 0·25, in very go agreement with the expectation.

This result shows that components *A* and *B* for a mixture under these conditions. It cannot b determined with certainty whether *C* and *D* for mixtures or solid solutions since the first part of th curve, where these components appear, is not suf ciently accurate. Either a smooth curve (sol solution) or two straight lines (mixture) fits th results within the experimental error.

Component *A* has been isolated from certa Cudahy preparations of high specific activity. Th solubility, as shown in Curve V, is very near th predicted for *A* from Curves I and III. This prepar tion was strictly homogeneous in the Tiselius electr phoresis cell (we are indebted to Dr. L. G. Long worth for carrying out this determination) and h the migration velocity and specific activity close that found by Tiselius *et al.* for the homogeneo protein present in the preparation analysed them[5]. It has no isoelectric point, as measured the collodion particle method, if the determinatio are made on a fresh solution. On standing, no protein nitrogen appears in solution and the particl become positive at *p*H 1·5. The *A* pepsin has be crystallized. The crystals are indistinguishable form from those previously described. The no protein nitrogen may be removed from the crysta by washing at 10° C. with

$$\begin{cases} M/10 \text{ acetate } p\text{H } 4\cdot0 \\ 0\cdot6 \text{ saturated magnesium sulphate.} \end{cases}$$

The *A* pepsin is much more unstable than *B*, that 10 hours' heating at 55° C. and *p*H 4·6 com pletely destroys it and changes the diagram of Cudahy preparation like that shown in Curve I one similar to that shown in Curve II.

Solubility diagrams of pepsinogen were found al to indicate several components. One pepsinog component present in only small quantities yields unstable pepsin which is nearly twice as active the pepsin previously obtained.

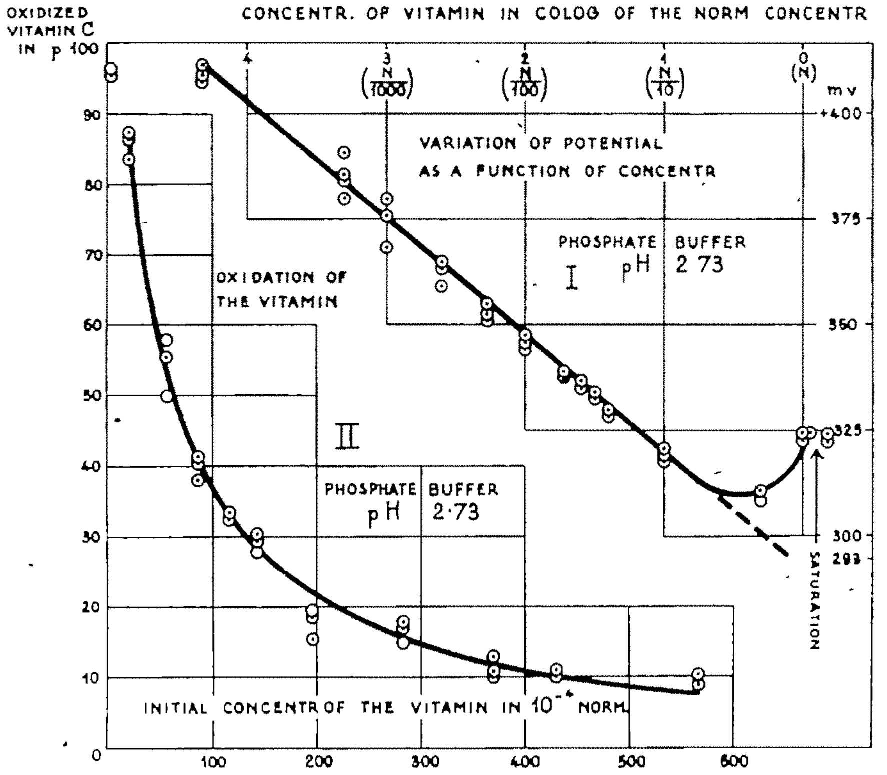
Platinum Potential of Vitamin C Solutions in Contact with Molecular Oxygen

THE platinum potential of solutions containing ological oxidation-reduction agents can be measured hen exposed to air by means of a relatively simple chnique[1].



CURVE I: SOLID LINE—EQUATION (2); RECTILINEAR PART OF SOLID LINE AND BROKEN LINE—EQUATION (1). VARIATION OF PLATINUM POTENTIAL AS A FUNCTION OF THE CONCENTRATION OF VITAMIN C.

CURVE II: SOLID LINE—EQUATION (3). VARIATION OF QUANTITIES OF OXIDIZED VITAMIN C AS A FUNCTION OF INITIAL CONCENTRATION. ON THE ABSCISSA: BOTTOM: CONCENTRATION OF VITAMIN EXPRESSED IN 10^{-4} NORMAL.

ABOVE: CONCENTRATION OF VITAMIN EXPRESSED IN COLOGARITHMS. ON THE ORDINATE; ON THE LEFT: AMOUNTS OF VITAMIN OXIDIZED, EXPRESSED IN PER CENT OF INITIAL CONCENTRATION. ON RIGHT: VALUES OF PLATINUM POTENTIAL EXPRESSED IN +MV.

We have established between the platinum potential E_1) and the concentration (C) of fresh solutions of corbic acid adjusted to a pH 2·7 (phosphate buffer) not pH 2·6 as stated before)[2], and exposed to air at 0° the following relations:

$$(1)\quad E_1 = 0\cdot 2925 \text{ volts} - \frac{RT}{2F} \ln C^{0\cdot 82} \text{ for concen-}$$

ations equal to or less than one tenth normal 7·6 gm. per litre);

$$(2)\quad E_1 = 0\cdot 309 \text{ volts} - \frac{RT}{2F} \ln\left(\frac{C^{0\cdot 82}}{(C^{1\cdot 17} + 0\cdot 52)^2}\right)$$

or all concentrations.

These equations do not take into account the versible reaction that seems to be very peculiar n this case. However, they express with a sufficiently ccurate approximation the ratio between the conentration of ascorbic acid in solution and the latinum potential of the same (see curve 1).

A study of the oxidation of vitamin in solution ept in contact with air, without stirring, for 24 hours at 37°, with a pH of 2·7 (phosphate buffer), gave the following equation:

$$(3)\quad (E_1 - 0\cdot 3534)\, 0\cdot 42 + \frac{0\cdot 00047}{0\cdot 3654 - E_1} = \log \frac{C_{\text{ox}}}{C_{\text{red.}}}$$

where C_{red} is the concentration of intact ascorbic acid, C_{ox} that of the oxidized vitamin, and E_1 the potential of fresh solutions at a temperature of 20°, as given by equations (1) and (2). The close agreement of the quantities of oxidized vitamin, both determined experimentally and calculated as a function of E_1 according to equation (3) (see curve II), shows that the values of E_1 were determined accurately.

Another argument in support of the relation set forth, between the dilution and the state of the ascorbic acid molecules, is given by Heintz[3]. This author has studied the infra-red absorption spectra of ascorbic acid present in the solid state and in 0·4 N and 0·1 N solutions (phosphate buffer, pH 2·7). Heintz finds that spectra of ascorbic acid present in the solid state and in the 0·4 N solution are similar; but that a marked change appears in the 0·1 N solution.

We call the potential E_1, as defined by equations (1) and (2), the potential of electronic affinity. This represents the tendency toward oxidation, that is, the reducing activity of ascorbic acid. The concentration of ascorbic acid checks its reducing activity, which determines the constant of the potential of solutions (pH 2·7 at 20°) near 0·4 *N*. In complex media, the vitamin activity can obviously be limited by factors other than its own concentration. In biological media with *r*H clearly above 16·2, the stability of ascorbic acid is due principally to this cause. In fact, it is known that the normal oxidation-reduction potential of ascorbic acid[4] corresponds to a *p*H of 7 with an *r*H of approximately 16·2, while the average value of the blood *r*H is[5] 20·8.

We wish to thank most cordially the Translation Service of the North Carolina State College, Raleigh, N.C., for help in the translation of this article into English.

Ozonization of *O*-Xylene and the Structure of the Benzene Ring

A. A. Levine and A. G. Cole[1] ozonized *o*-xylene and were able to isolate diacetyl from the reaction product, while methylglyoxal and glyoxal were isolated in the form of the osazones by means of *p*-nitrophenylhydrazine. This result is of great importance for the theory of the structure of the benzene nucleus. In their paper, Levine and Cole give no evidence about the yield of the substances isolated. Therefore we have reinvestigated this reaction using another analytical method. We have transformed the decomposition products of the ozonides into the corresponding oximes and we have worked out a method for separating the oximes quantitatively.

O-xylene (solidification point − 27°) was ozonized in chloroform solution at − 25°, using oxygen with 2·5 per cent ozone until about the calculated quantity of ozone had been taken up. From the reaction product we isolated:

(1) The oxime of dimethylglyoxal melting at 233–234°, mixed melting point with an authentic sample (m.p. 234–235°) 233·5–234°. (2) The oxime of methylglyoxal melting at 150·5–151·5°, mixed melting point with an authentic sample (m.p. 152·8–153·1°) 152–152·5°. (3) The oxime of glyoxal melting at 170·5–171·5°, mixed melting point with an authentic sample (m.p. 172·5–173°) 171·2–172°.

The yield of oximes amounted to about 20 per cent of the theoretical yield calculated on *o*-xylene. The composition of the mixture was roughly determined as follows: 0·88 mol. of dimethylglyoxime, 2 mol. of methylglyoxime and 3·2 mol. of glyoxime, while the calculated ratio should be 1 : 2 : 3, if th
two Kékulé forms each contribute 50 per cent
the structure of *o*-xylene. It will be necessary
improve our analytical method before we can gi
the exact value for the molecular ratio of the oxime

The work of two independent groups of worke
now affords chemical evidence for the occurrence
o-xylene of two resonating Kékulé structures. Th
investigation is being continued from the quantitati
point of view; full details will be published in th
Recueil des Travaux Chimiques des Pays-Bas.

Photo-oxidation of Pyrrhole

FRESHLY redistilled pyrrole dissolved in wate
alcohol or acetone and mixed with $0 \cdot 5 \times 10^{-4}$
methylene blue rapidly takes up oxygen in the lig
but not in the dark. Pyrrole alone is not oxidize
The rate of oxygen uptake is a linear function
light intensity. Eosin, but not fluorescein, can
used instead of methylene blue. Tests with standa
optical filters showed the effective wave-lengths
be within the range of 5200–5800 A. On the ba
of 5500 A., the energy necessary to institute th
reaction is $3 \cdot 4 \times 10^{-12}$ ergs/molecule.

Two atoms of oxygen are taken up per molecu
pyrrole. There was no decarboxylation or deamin
tion. The methylene blue was removed by a minim
amount of charcoal and the solution evaporated
dryness. The residue was extracted with aceto
which on evaporation left crystals. These we
recrystallized several times from boiling benzen
The analysis was C, 49·1 per cent, H, 5·3 per cen
N, 14·1 per cent; m.p., 102·5°; yield, 58 per cen
Mixed melting point determinations showed th
the substance was not succinimide. On alkali
hydrolysis, it yielded 14 per cent ammonia nitroge
and 72 per cent succinic acid.

n-methyl and *n*-ethyl pyrrole are also oxidize
under the same conditions, but only one atom
oxygen is taken up per molecule.

Crotoxin

IN May of last year[1] we announced that we ha
been able to purify and crystallize the chief tox
principle of rattlesnake venom, which we calle
crotoxin. Crotoxin contains the whole neurotox
and hæmolytic activity of the crude venom; bu
both have a 25 per cent greater activity than th
crude.

The following are the main points of evidence th
crotoxin is a pure and homogeneous substance:

(1) The analytical data[2] obtained from differe
samples of crotoxin at different times are the sa
(C: 50·77 per cent and 50·56 per cent; H: 6·41 p

nt and 6·47 per cent; N: 15·86 per cent and 4·90 per cent; S: 3·96 per cent and 4·03 per nt).

(2) Five recrystallizations of crotoxin did not alter neurotoxic and hæmolytic activity.

(3) The solubility curve of crotoxin at different nmonium sulphate concentrations[3] shows the raight line typical of pure substances[3].

(4) Gralén and The Svedberg[4] were able to show at crystalline crotoxin in the ultracentrifuge "be-yed in sedimentation and diffusion as a homoneous substance".

Recently Gosh and De[5] reported one experiment: solution of 100 mgm. of crude rattlesnake venom crete was saturated with sodium chloride. After anding for one night at 6° a precipitate was obtained hich contained 8–10 per cent of the original hæmotic and 2–2·5 per cent of the neurotoxic activity. rom this difference of the ratio of neurotoxic to emolytic activity in such a precipitate, the Indian thors conclude that our crystalline crotoxin cannot a homogeneous substance.

We see no reason to discuss such experiments ecuted with the crude venom secrete since we have ready shown how to crystallize the active principle rattlesnake venom, easily and in good yield.

Cytology of the Common Male Fern in Britain

IN a paper which has just come to hand by Döpp[1], tological observations of some importance are given ith regard to the genus Dryopteris (= Lastrea = ephrodium) in Europe. In particular, and among ther things, apogamy is reported in "*D. paleacea*" om four localities in Germany and Switzerland and e chromosome number in one of these plants is ven as "*c.* 130" in contrast to the sporophytic umber for normal *D. Filix-mas* which was preiously found by the same author to be *c.* 160[2].

These observations are so closely cognate to a large ody of work which has been in progress for some ars on the British fern flora, that it may perhaps void a profitless duplication of effort, if the main ots which I have obtained for *D. Filix-mas* (*sensu ta*) in Britain are summarized in advance of the ain paper.

So long ago as 1855[3], a very shrewd field collector, ollaston, expressed the view that at least two of e varieties described for the male fern in Great ritain, namely, the varieties *Borreri* and *abbreviata* Newman, were worthy of specific rank. Newman's rietal names were regarded as synonymous with e varieties *paleacea* and *pumila* of Moore; but to nphasize the idea of specific distinctness Wollaston troduced two new terms, namely, *pseudo-mas* and *opinqua*[4]. These have never penetrated deeply to purely botanical literature, but they have been (and still are) widely used by amateurs and fern collectors in Great Britain. They are a commonplace of English pteridological handbooks of the older school (for example, Druery[5]) and are represented in the *L. pseudo-mas* var. *polydactyla* Wills and Dadds quoted by Dopp. By modern rules of nomenclature both *pseudo-mas* and *propinqua* are illegitimate, since priority rests with the names of Newman. In view of their historical importance, however, it is necessary that their meaning should be understood.

My own work on this subject began in 1936 with the discovery of an apogamous plant from central Ireland with *c.* 120 chromosomes. This plant was identified by Mr. Alston of the British Museum as *D. Filix-mas* var. *Borreri* Newm. The cytological findings were at that time so unexpected that field investigations were at once undertaken in order to elucidate them. In the three years which have elapsed, cytological observations have been made on nearly one hundred plants from more than twenty localities in England, Scotland, Ireland and Wales. In carrying out this field exploration, Wollaston's classification has been found to be of the greatest service and has indeed been the only one which could immediately be applied to the problem. The results are as follows:

(1) Wollaston's *L. propinqua* (= *abbreviata* Newm). has been obtained from England, Ireland and Wales. It reproduces sexually and has a gametic chromosome number of 40–41. This number I regard as haploid and the sporophytic number (*c.* 80) of this form as diploid.

(2) Wollaston's *L. Filix-mas* proper, the commonest hedgerow type in England, also reproduces sexually, but has a sporophytic chromosome number of *c.* 160 (as previously reported by Döpp)[2]. This number I regard as tetraploid; but the meiotic behaviour is not that of a recent auto-tetraploid.

(3) Wollaston's *L. pseudo-mas* (= *Borreri* Newm. = *paleacea* Moore) appears to be exclusively apogamous and therefore contains a potentially infinite variety of true-breeding strains. My own first plant with *c.* 120 chromosomes and presumably also those of Döpp ("*c.* 130") I interpret as triploids. Local populations of diploids, with *c.* 80 chromosomes and tetraploids with *c.* 160, all apogamous and with the morphology of *pseudo-mas*, have since been met with and there may be still higher polyploids to be discovered.

There is strong evidence to suggest that all three of Wollaston's types can hybridize; but I do not consider this to invalidate the conclusion that they could and should be regarded as three distinct species. I therefore agree with Döpp's desire to accord specific rank to *D. paleacea* though this is clearly only a part of a larger problem.

While further discussion must be left to the fuller statement, a word of appreciation may perhaps be allowed here for the abilities of a man like Wollaston who, with only the morphology to guide him, should have correctly divined these relationships, against the views of contemporary botanists.

I. MANTON.

Role of the Renal Innervation in Kidney Function

OBSERVATIONS have been made on the role of the renal innervation in kidney function. A dog's kidney was transplanted to the inguinal region by end-to-end anastomosis of the renal vessels to the femoral; the bladder and distal ureteral orifices were exteriorized. Convalescence was uneventful and both kidneys gave every tested physiological evidence of normal function. During antidiuretic, that is, normal, urine flows, the rate of urine flow and of glomerular filtration is greater in the transplanted kidney than in the untransplanted kidney of the same animal. Following administration of a large quantity of water or of a small dose of adrenalin, the above differences become strikingly reversed; this strongly suggests that the transplanted kidney has continued to be effectively denervated. It was demonstrated that phenol red, water and chloride secretion are pra tically identical in both kidneys *per unit volume glomerular filtrate*. Cogent evidence is present indicating that adrenalin normally acts indirectly the vas efferens of the glomerular vascular tufts, th is, only by way of the renal nerve supply, and th "pituitrin" acts directly on the tubules. The wo will shortly be published in full.

Points from Foregoing Letters

Absorption experiments have been made in lead and air of the primary radiation responsible for the heavy particle component of the cosmic rays. It is shown by W. Heitler, C. F. Powell and G. E. F. Fertel that this primary radiation consists neither of electrons nor mesotrons, and it is suggested that the best working hypothesis is provided by the assumption that the heavy particles are produced by neutrons. An atomic 'explosion' has been observed in which one of the fragments consists of a highly charged nucleus with a very great specific ionization and showing marked effects due to 'capture and loss'.

A. and E. Vassy infer from computations of the mean temperature of atmospheric ozone, which agree with radio-sounding measurements, that in arctic countries the stratosphere is very hot in summer and very cold in winter; the higher the altitude, the greater the difference between the extreme temperatures.

M. E. J. Gheury de Bray states that the velocities of recession of extra-galactic nebulæ are so large as to throw doubt on their reality. An alternative explanation of the red-shift is proposed, based on the fact, shown by every observation made during the last half century (seven determinations), that the velocity of light decreases with time.

C. H. Douglas Clark has extended his work on the relation between dissociation energy and internuclear distance of carbon-carbon linkages to di-atoms of the HH, KH and KK periods in ground states. It is found that, with the aid of a relation due to Sutherland, this leads to new functions involving bond constant and internuclear distance, having characteristic values in given periods for di-atoms of similar electronic configuration. It appears that extension to excited states is possible.

G. W. Scott Blair and Miss F. M. V. Coppen have shown that the compression moduli of nearly elastic rubber cylinders can be subjectively distinguished with three times the accuracy obtaining in the case of the viscosity of truly fluid bitumens, and have found certain significant differences between subjects having different types of training.

Minute nodules containing vanadium have been found by J. Newton Friend and R. H. Vallance in the Keuper marls of Worcester. They are surrounded by a greenish aureole in the red marl and, in composition, resemble the larger nodules found in t red Permian marls of Budleigh Salterton.

In reactions in organized condensed systems, t rate of reaction is given by the Polanyi-Wign equation when but few molecules or chemical bon are involved in the unit process. In order to accou for the high rates of reaction met with in a numb of complex processes, comparative activation is su gested by W. E. Garner as a possible mechanism.

V. Desreux and R. M. Herriott have analys several commercial pepsin preparations by t solubility curve method. Measurements showed th at least three or four active proteins are prese which differ from each other in solubility, stabilit and specific activity. One of the active componen was isolated in solubility pure form and crystalliz The proportion of the components varied in t different commercial preparations.

N. Bezssonoff and Mme. Woloszyn give the equ tion of platinum potential as a function of concentr tion of ascorbic acid in fresh solution in contact wi oxygen. The potential becomes practically stab when the reducing activity of the vitamin is check by its own concentration. Inhibition of this activi by factors other than concentration explains t presence of intact ascorbic acid in biological med where the oxidation-reduction level is very high.

From the reaction product obtained by the ozoni tion of *o*-xylene J. P. Wibaut and P. W. Haaym isolated dimethylglyoxime, methylglyoxime a glyoxime in a molecular ratio of about 0·88 : 2 : 3 and a total yield of about 20 per cent calculated *o*-xylene. This result, which corroborates the qualit tive results of A. A. Levine and A. G. Cole, giv evidence for the occurrence of two resonating Kéku structures in *o*-xylene.

According to F. Bernheim and J. E. Morgan pyrro is rapidly oxidized in the presence of methylene bl and light. A substance of unknown structure is form which on hydrolysis yields succinic acid and ammoni

Cytological evidence is quoted by I. Manton reply to a paper by Döpp to show that the comm male fern (*Dryopteris Filix-mas*) in Britain real consists of three distinct species, one of which sexual and diploid, another is sexual and tetraploi while the third is apogamous and contains a varie of polyploid forms.

RESEARCH ITEMS

Aboriginal Races of India

B. S. GUHA in a racial analysis of the aboriginal peoples of India (*Science and Culture*, 4, 17, June, 939) points out that of the inhabitants of all India, 22¼ millions, in round numbers, are still in a primitive state, living by hunting, fishing and on forest produce, and forming 6¼ per cent of the entire populaion, but that if to these are added the fifty millions and more of the so-called "exterior castes", who are mostly detribalized primitive folk in process of entering the Hindu social system, the proportion becomes twice or even thrice this figure. Regionally hese tribes are grouped into three separate zones. 1) A northern and north-eastern division of about hree million people, scattered over a very large area of the sub-Himalayan region and the mounainous territory of Assam and north-eastern India, and merging into those of Burma and Yunnan. 2) A central division occupying small hills and plateaux traversing the entire breadth of the country from the Gulf of Cambay to the Orissan coasts, and omprising the Bhil, Gond, Kol, Oraon, Munda-Santal, etc. (3) The southern division, the smallest, ontaining little more than a hundred thousand people, spread over the hills of southern India, especially he extreme south-western strip. There is a rough parallel between the geographical distribution and the linguistic affinities of these peoples. Among the northern and north-eastern group the languages are of the Tibeto-Chinese family, with certain small exceptions. In the central division the languages poken belong chiefly to the Munda branch of the Austric family, though certain peoples have adopted Aryan and Dravidian tongues. The southern group now speak entirely Dravidian languages in corrupt forms; and in the absence of a linguistic survey here is no means of knowing whether any traces of heir original languages, Austric or other, survive. The same parallelism, however, does not exist in physical features, which show strains of Negrito, Proto-Australoid, a brachycephalic element with two ubdivisions, one being more primitive than the other, and fourthly a medium-statured dolichocephalic element chiefly distributed in the Assam hills and mixed no doubt with short-statured Palae-Mongols.

Negro Education in the United States

AN analysis of the statistics of negro education in he United States of America for the years 1933–4 and 1935–6 by David T. Brose and Ambrose Caliver U.S. Department of the Interior, *Bull.* 1938, No. 13) collects evidence of progress in dealing with one of he vital population problems of the country. Despite he depression, remarkable advance was made beween 1933 and 1936, as also in the two preceding decades, more especially in the number of public high schools and their enrolment. In 1915, 58 per cent only of the negro children were enrolled in school; in 1930, the percentage had risen to 84; and in 1936 it is probably greater. This increase repreents, among other things, a growing appreciation by the negroes of the value of education in the olution of their problems. It is now recognized among them that "the improvement of the rural and urban masses in health, honesty, labour and thrift is directly dependent on the public elementary school". Among definite results illiteracy has been reduced from 30 per cent in 1910 to 16 per cent in 1930. The number of elementary and secondary school enrolments in 1935–6 totalled 2,438,981, being 24·2 per cent of the total negro population of 18 States. This is a slight decrease from 24·5 per cent in 1931–2, but represents a slight increase from 81 to 82·8 per cent of the negro child population between the ages of five and seventeen years. The fluctuation between 1917–1936, probably due to economic causes, shows a definite upward trend for six years following on the Great War, a recession in 1924–28, followed by a sharp rise in the boom years 1929 and 1930, with a continued high percentage in the years of depression, due in part to lack of employment, in part to assistance from public funds. The number of schools in 1935–6 is public elementary, 24,405, public high schools, 2,305, the latter a great development from 64 in 1915–16.

Human Schistosomiasis and its Intermediate Hosts

DR. ALAN MOZLEY (*Trans. Roy. Soc. Edin.*, 59, No. 26; 1939) has described twenty-six species of freshwater molluscs from Zanzibar, Pemba and Tanganyika Territory as a preliminary to the study of the species concerned with the transmission of the parasite causing schistosomiasis in man. Although the infection is slight when compared with conditions in Egypt, yet its effects are considerable, and might, in the opinion of the author, be brought under control by extermination of the molluscs over infected areas. In Zanzibar and Pemba, 10–70 per cent of the natives are infected with *Schistosoma hæmatobium*, while in Tanganyika *S. mansoni* is the prevalent parasite. Mozley suspects that *Physopsis globosa* (Morelet) transmits *S. hæmatobium*, and was able to prove experimentally that *Biomphalaria pfeifferi* carries *S. mansoni*. He describes the general ecological conditions governing the life and distribution of freshwater molluscs in the area, noting that as a result of these conditions the distribution is strictly limited to a small proportion of the ponds, lakes and streams. He discusses control methods involving destruction of the molluscan intermediate host, recommends drainage, flushing and chemical means, but considers that plant poisons and biological control methods are not yet fully worked out. He is optimistic, however, that the disease could be stamped out in Zanzibar within five years, and over the whole area in a somewhat longer period.

Pleiotropic Gene-effects in the Rat

H. Grüneberg, 1938, and H. B. Fell and H. Grüneberg (*Proc. Roy. Soc.*, B, 125, 123–144, and 127, 257–277; 1939) have investigated the effects of a gene in the rat which, in the homozygous condition, causes the death of the individual. About the time of birth the rib cartilages become abnormal (formation of thick capsules around the cartilage cells, and a very active cell proliferation). These abnormalities give rise to secondary symptoms the intensity of which differs in different individuals. The abnormal thickening of the rib cartilages leads to a distortion of the thoracic basket and internal organs. Respiratory rib movements become impossible. As a consequence, emphysema of the lungs and sometimes compensating collapse in some regions of the lungs develops. Heart trouble occurs regularly as a consequence of the emphysema. Death occurs suddenly or slowly, depending on the type of cardiac failure which is induced, and not infrequently due to hæmorrhages into the lungs. Other deaths are caused by an inability to clean dirt from the nose which is normally brought about by sneezing. The presence of dirt prevents effective suckling, and starvation results. By reciprocal transplantation and tissue culture methods, it is shown that the abnormality of the cartilage is self-differentiating in post-embryonic life.

Vegetative Propagation of a Fern

The number of vascular cryptogams which can be propagated vegetatively is remarkably small, but a recent short paper by E. E. Kemp (*Gard. Chron.*, July 15) describes an unusual method of regeneration from isolated, swollen leaf-bases of the fern *Marattia fraxinea*. These organs, which persist on the plant after the leaves have fallen, were placed on the surface of a coco-nut fibre rooting medium in a propagating case with a bottom temperature of 80° F. Buds then formed on the abaxial surface, either upon the leaf-base itself, or upon one of the stipules. When the buds had produced several roots from the base, they were removed and grown separately, still in the propagating case. The method offers one of the most economical means of vegetative propagation, since the old leaf-base will continue to produce additional buds until its stores of food become exhausted.

Smut Fungi of India

A paper by B. B. Mundkur (*Trans. Brit. Mycol. Soc.*, 23, Pt. 1, 86-121, May 1939) gives the results of a critical re-investigation of forty-four collections of Indian smut fungi in the Herbarium Cryptogamæ Indiæ Orientalis of the Imperial Agricultural Research Institute at New Delhi. Only twenty-five species are represented in the collections, but seven of these are now described for the first time, and five are new taxonomic combinations. The new species are *Ustilago polytocæ*, *U. barberi*, *Sorosporium pennisetii*, *S. avmatii*, *Sphacelotheca dinebræ*, *S. sahayai* and *Tilletia ajrekari*. The collections are not exhaustive, for 110 species of smut fungi are recorded for India. These new species are, however, parasitic upon plants which are peculiar to that region, and it is gratifying to see such progress in their critical determination as is revealed by the paper under review.

Solubility of Cements

A publication by the Department of Scientific and Industrial Research, "The Solubility of Cements", (Building Research Technical Paper No. 26. London: H.M. Stationery Office, 1939, 6*d*. net), describes some investigations made for the Joint Sub-Committee on Special Cements of the Institution of Civil Engineers and the British Committee on Large Dams. The report deals with the deterioration of cements when exposed to certain types of waters, especially soft waters common in many mountain areas, and tests made with five types of cement show that the extractio tests on ground set cements, developed originally i Sweden, afford a simple measure of their susceptibilities to attack adequate for practical purposes.

Physics Research at Harvard

Vol. 4 of Series 2 of *Contributions from the Physica Laboratories of Harvard University* for the year 193 includes fifty-four papers which have appeared in th *Physical Review* and other scientific periodicals up t March 1938. About 18 per cent of them are from th high pressure laboratory of Prof. Bridgman in whic the physical properties of substances at pressures o the order of 45,000 atmospheres are being investigated about 11 per cent from that of Prof. Van Vleck whic deal with magnetic susceptibilities and dielectri constants; 9 per cent from that of Prof. Pierce whic deal with vibrations and supersonics, and others fro the laboratories of Profs. Bainbridge, Oldenberg an Street dealing with mass spectra, molecular spectra radioactivity and cosmic rays respectively. I addition, there are papers by other members of th staff and by seven fellows either of Harvard o national research fellows, and Dr. E. H. Hall ha two papers on the four transverse magnetic effect which he has measured with greater accuracy tha has been possible hitherto. With the staff availabl at Harvard a wide field of research can be covered and the amount of work done is impressive.

The Absolute Ampere

Since the decision of the International Committe on Weights and Measures in 1927 that the materia standards for all electrical units should approximat as closely as possible to the absolute theoretical units the standardizing laboratories of the world have bee determining with the precision now available th values of their concrete standards in terms of th absolute units. The International Ampere was defined at the London International Conference in 190 as depositing 0·001118 grams of silver per second The precise measurement of current depends i practice on the use of a potentiometer, a standar ohm and a standard cell, which each laborator possesses. The comparison between the ampere s measured and the absolute ampere as measured b some form of current balance has been made i several of the most important national laboratories That made recently at the Bureau of Standards b H. L. and R. W. Curtis and C. L. Critchfiel is described in Research Paper R.P. 1200 of th Bureau. By means of an improved form of Rayleig balance, they find that the Bureau Internationa Ampere is 0·99986 absolute amperes, which agree exactly with the result obtained at the Nationa Physical Laboratory three years ago for the N.P.L. International Ampere.

Balloon Experiments in High Latitudes

H. Carmichael and E. G. Dymond (*Proc. Roy. Soc.* A, 171, 321; 1939) have now published the result of their balloon experiments made near the geomagnetic pole in North-West Greenland (see Nature 141, 910; 1938). The primary object of the experiments was the determination of cosmic ray intensitie at high altitude, and two forms of apparatus wer used: a coincidence counter set which transmitte wireless signals during its flight and which did no need to be recovered, and a photographic recordin ersion of the 'ticking' quartz fibre electroscope. The alloon technique was based on that of Regener, and everal flights were made with both sorts of apparatus p to about 20 km. The results, when compared ith those of other workers at lower latitudes, indicate hat there is practically no increase in the cosmic adiation incident at the top of the atmosphere between eomagnetic latitude 50° and the geomagnetic pole. ince cosmic rays of low energy, between $3 \cdot 10^7$ and $\cdot 10^8$ ev., would be admitted in increasing numbers y the earth's magnetic field in this region, it must e concluded that no rays of low energy reach the arth from outer space. They may, perhaps, be cut ff by some external magnetic field such as that of the un. The expedition obtained a good deal of aero-gical data from the flights made by the apparatus nd incidentally with pilot balloons. The stratosphere ind speeds found on this summer expedition were ery low and the apparatus often descended near its tarting point. The tropospheric wind speeds showed well-defined maximum at about 9 km., probably ust below the tropopause. A meteorograph flight howed a well-marked tropopause at 11·2 km. and n unusual rise of temperature in the stratosphere.

eflectivities in the Ultra-Violet

G. B. Sabine (*Phys. Rev.*, 55, 1064; 1939) has ade an investigation of the reflecting power of a umber of evaporated metal films in the wave-length egion from the visible to λ 450 A. Aluminium has high reflecting power down to λ 2000 A., which falls ff steadily at shorter wave-lengths. Below 1200 A. is exceeded as a reflector by several metals. Silver, e is well known, reflects very little in the neighbourood of 3000 A. Below this its reflectivity rises again. ts value in the region of 1000 A. is about 10 per ent, and is higher than that of most metals. Platinum the best mirror found for wave-lengths less than 200 A., and its reflectivity from 1200 A. to 400 A. aries from about 15 per cent to about 8 per cent. ata are also given in the form of reflectivity curves r Pb, Mn, Be, Fe, Pd, Ni, Ti, Au, Cd, Zn, Te, Mo, r, Bi, Mg, Cr, Sb, Cu.

eneral Analysis

This striking analogies between apparently unlated branches of mathematics led the late E. H. oore to assert that there must be a general theory, hich he called general analysis, underlying these articular theories and unifying them. His first ttempt to develop such a theory was of a postutional nature. This is fully accessible in his published apers. His second attempt, of a more constructive pe, occupied him from 1915 until his death in 1932; ut it has hitherto been described only in fragmentary rm and in scattered papers. The American Philophical Society has now undertaken to present a full count of the theory. The first part appeared in 35, and dealt with the algebra of matrices. The cond part, the fundamental notions of general alysis, appeared this year. There are two more rts still to come, generalized Fourier series and odular spaces, and the characteristic value problem general analysis. The work has been carried out R. W. Barnard, who has revised Moore's notes d provided an introduction to each chapter, so as render as easy as possible the comprehension of hat must, in view of its generality, necessarily be a ghly abstract theory.

Fission of Rotating Bodies

R. A. Lyttleton has published a paper (*Mon. Not. Roy. Astro. Soc.*, 99, 7; May 1939) replying to K. E. Edgeworth's criticism of some of his views (see Nature, July 8, p. 81). Lyttleton points out several inaccuracies in certain dynamical principles in Edgeworth's paper, and a few of these are worthy of notice. Edgeworth believes that in the rapid and continuous transition of a satellite from a circular to a parabolic orbit the kinetic energy at a selected point on the latter orbit must be considerably greater than that possessed in its original circular orbit. Lyttleton shows that this is incorrect; the energy of escape varies inversely as the distance apart of the components and the kinetic energy in circular motion is half the kinetic energy in parabolic motion at the same distance. Using the figures which were given in Edgeworth's paper, the amount of energy possessed by the satellite in the circular orbit is about four fifths the energy that it has in the parabolic orbit—not a great difference and considerably less than Edgeworth estimated. In addition, it is shown that the direction of the force required to produce parabolic velocity should be nearly perpendicular to the direction drawn by Edgeworth in his paper. This force is actually radial in direction and is due to pressure, and no mention of this pressure is made by Edgeworth. Lyttleton next shows that the process of fission described by Edgeworth is open to serious doubt. When Jeans suggested the mechanism of the initial development of the pear-shaped figure in 1928, it was not then generally recognized that the pear-shaped figure is ordinarily unstable, and in point of fact the pear-shaped series of figures does not come into existence. Irrespective of this, the details of the process of fission developed by Edgeworth are open to doubt. In particular, why should the spiral arm just extend to Roche's limit, and why should the velocity be such that the tip of the arm does not come within the limit again and suffer disruption? These and other objections seem to impair very seriously the validity of Edgeworth's criticism of certain views advocated by Lyttleton.

Twelve New Southern Variables

Mr. J. B. G. Turner has given a brief description of his discovery of twelve southern variables with the Victoria 24-inch telescope, Cape of Good Hope (*Mon. Not. Roy. Astro. Soc.*, 99, 7; May 1939). The plates taken for parallax determination consist of upwards of twenty-five, divided nearly equally among five epochs of observation, an epoch representing at least four weeks. A plate of good definition was selected as standard, and the remaining plates were in turn superposed upon it so that the star images of the upper plate were brought into proximity to, but not exact coincidence with, the corresponding images of the standard plate. The resulting pairs of images were then examined for evidence of variation. When a star was suspected of variability, comparison stars were selected as close to it as possible, and when their magnitudes were established, the magnitude of the variable was determined from a comparison of the size and density of its image on each plate with those of the comparison stars on the same plate. A description is given of the method finally adopted for the determination of the magnitudes of the comparison stars, which proved very satisfactory.

RECENT ARCHÆOLOGICAL EXCAVATIONS IN EGYPT

THE Merimda Civilization. Results of importance for their bearing on stratigraphical relations and development in culture were obtained in the excavations of the Academy of Sciences on the prehistoric site of Merimda-Beni Salama, west of the Nile Delta, which lasted from January 25 until April 4, 1939. In this season—the seventh devoted to this site—it has been demonstrated that of the various levels each corresponds to a different stage of development, contrary to the earlier conclusion that the Merimda civilization was uniform throughout. Although, it is true, the population did not change, and the mode of life throughout was the same—the practice of agriculture, combined with stock-breeding and hunting—while their weapons and tools were similar, and their burial customs identical, yet it is now possible to trace development.

Three levels of occupation can be distinguished. The first is a wide stretch of sand, yellowish in colour, on which the inhabitants lived in lightly constructed huts, too widely spaced to prevent the invasion of the sand, in which the hearths are visible in black, while the interments are shown by greyish tints. The second level is of a light grey colour, showing a series of superimposed surfaces, hardened by occupation. The constructions were closer together, and of a more solid character. The third layer is of a deep blackish colour, consisting in the main of the debris of human habitation, in which the proportion of sand is very much less than in the earlier levels. The settlement evidently was a much closer agglomeration of structures, oval in shape and constructed of lumps of clay, which make their appearance for the first time together with large baskets for cereals. These baskets were buried in the earth, and are replaced later by large pottery jars. The evidence shows a development from a scattered occupation to a compact town, traversed by streets.

It has now been established that numerous types of pottery found in the primitive settlement are perpetuated throughout the whole duration of occupation, but that others disappear in the course of development. Such, for example, is the fate of fine basins of a hard clayey material, with a brilliant red polish on the exterior, except for an unpolished horizontal band engraved with a palm-leaf motif. This is found more rarely and of inferior quality in the second layer, and disappears, and with it the palm-leaf motif, in the third. Next season's work will be devoted to working out further evidence of development on these lines.

Saqqara. During the last two or three seasons, the excavations by the Antiquities Department of the Step Pyramid at Saqqara have been intermitted in the interests of clearance and preservation. In the past season, M. Lauer has been engaged in clearing the great court, measuring 180 m. by 100 m., at the south of the pyramid. The clearance resulted in the discovery of fasciculated column drums of the colonnade in process of being restored, portions of boundary stones inscribed with the names of Zoser and the princesses Hetep-her-nebti and Int-ka-s, and a small fragment of the statue of Zoser with the titles of Im-hotep belonging to the statue foun twelve years ago.

Among other finds were three little granit statuettes of the Fifth Dynasty, which had bee stolen by robbers but abandoned. Two of the represent the same person standing. They be traces of colour on the head, the eyebrows, the eye and the nails, the granite representing the skin. T clothing was also painted. The third statuette black granite also bears traces of colour, and inscribed with the name of Her-en-kaw, direct of the scribes of the textile fabrics. A hea of a woman in stuccoed and painted wood foun near by, which seems to date from the New Kin dom, shows a pair of earrings which are painted blac

Before the close of the season, the clearance w completed of the south side of the Pyramid of Un and of the contour of his funerary temple. Eviden was then brought to light that Unas, in order build his own pyramid, had completely destroyed t funerary monument of his predecessor Dadkar This action, taken in conjunction with the eviden of certain inscribed material, found in the course the work, raises the important historical point as the identity of the ruler responsible for the chan of dynasty usually attributed to Teti. To th question no answer can yet be given.

Tuna el Gebal (Hermopolis West). Excavations this site by the Fouad I University, which last seas had been occupied with material of the Ptolema period, were again pushed forward in Gallery *C*, a by the end of the season had reached the period Psammetichus and Amasis. On clearing the galler an interior room cut below it appeared. Here, in further chamber, a remarkable discovery was that a sarcophagus. Previous evidence suggested th these galleries had been reserved for the mummi of ibises and baboons; but the sarcophagus prov to be that of a prince and chief priest of Hermopol The chamber was filled with canopic jars of alabast covered with inscriptions, and placed in pairs either side of the sarcophagus. Their covers we carefully sculptured with the heads of the fo "Sons of Horus". At the right of the sarcophagus the foot were 400 blue faience statuettes (ushabt inscribed with the name of the high-priest Ankh-ho while on the east side were several blue faience vas containing unguents, fruits, and gilded leaves. T sarcophagus contained a mummiform coffin of woo The mummy wore a mask of silver and a band gilt leather on the chest. On both sides of the bo were two sheets of gilt bronze bearing in relief figu of the four "Sons of Horus". The mummy lay wi head to west.

Another corridor filled with jars which, apparentl had not been reached by robbers, yielded 1 statuettes of Osiris in bronze, statuettes of isis, a of the bull, while among the finest pieces was prince of Hermopolis standing between the goddes Isis and Nephthys with Horus in front of him on lotus column, flanked by the two uraei of Upper a Lower Egypt. This ensemble is before an Ibis seat on a stand, sculptured and set with stones of ma colours imitating lotus flowers.

EARTHQUAKE INSURANCE

By E. TILLOTSON

ENERALLY speaking, earthquake insurance is still only undertaken in very few cases and ually with reluctance by underwriters. This is derstandable in that exact statistical evidence only ists in the majority of cases over a period of ± 10 years, which is insufficient to make it possible judge when another shock is likely to take place any particular locality. Moreover, in the present ate of knowledge, earthquakes cannot be predicted actly by any other means. It is, however, possible indicate which areas are more likely to experience rthquake shocks than others, and it should there- re be possible to initiate some sort of insurance ainst these natural calamities.

Further difficulties are, first, to envisage how much mage is likely to be done by a shock, and secondly, build up sufficient reserves of capital to cover the sses. Given sufficient interest on the part of property wners in this type of insurance, mutual assistance companies and perhaps initially Government aid companies undertaking earthquake insurance, the estion of reserves of capital could be solved and e companies could then proceed to formulate emium rates. One may suppose that these will be verned in any particular case by several factors ch as expectancy of occurrence of shocks, type of ilding, amount of coverage, and an additional sum r expenses, profit and reserves.

The expectancy of occurrence of shocks varies, cording to the locality and can at best only be aluated roughly. As example, it appears that in pan there may be a severe shock every three or ur years, whilst in the United States it has been timated that there is a strong shock approximately ery twenty-five years with a tendency for it to cur in the west rather than in the east. In Great ritain, scarcely any damage is done by earthquakes all.

Buildings vary greatly from the steel-framed inforced concrete buildings of low altitude such as ose designed by Dr. Tachu Naito, of Tokyo, which ffer very little in any earthquake, to concrete block ildings and the native huts of tropical countries, hich are often completely razed. Between these tremes, buildings offer various degrees of resistance earthquake shocks, and it would not be difficult the light of knowledge gained in previous shocks classify buildings according to the extent to which ey would be likely to be damaged should an earth- ake of known intensity occur.

The type of ground on which a building rests also s an important effect on its resistance to earth- akes. Structures on unconsolidated sand or swamp ffer much more severely than those of similar sign built on solid ground or rock. Also buildings er old faults are particularly liable to damage, as e faults nearly always renew their movement during earthquake. For these reasons the advice of a ologist would be very valuable to any company dertaking earthquake insurance risks.

It is usual in all cases of insurance to calculate nual premiums from the formula

$$P = Cp,$$

where P is the annual premium, C the amount of covering and p the probability of occurrence of the disaster. It has been shown by Marchant that this formula may lead to

$$P = \int_A^U y\,x\,dx + U\int_U^V y\,dx,$$

where y is the probability factor that the sum of money involved in the accident be just x, V the total value of the goods and buildings involved in a possible accident, A the value of the goods not insured, and U the upper limit of payments guaranteed by the assurer. The difficulty in the case of insurance against earthquake hazards is to determine the form of y. Working purely on a statistical basis, he proceeds as follows: At any particular time in the given locality, let the total value of the insured goods be G, and during T years determine from statistics

n_1 years during which the earthquake damage was less than $G/10$;

n_2 years during which the earthquake damage was between $G/10$ and $2G/10$;

n_3 years during which the earthquake damage was between $2G/10$ and $3G/10$.

. . . .

n_{10} years during which the earthquake damage was between $9G/10$ and G.

The probabilities that the occurrences may fall into the above categories may be estimated as

$$p_1 = n_1/T = \int_0^{G/10} y\,dx\,; \quad p_2 = n_2/T = \int_{G/10}^{2G/10} y\,dx$$

$$p_3 = n_3/T = \int_{2G/10}^{3G/10} y\,dx$$

. . . .

$$p_{10} = n_{10}/T = \int_{9G/10}^{G} y\,dx\,;$$

from which we obtain by approximation,

for $x = G/20$ $\quad y = 10p_1/G$

for $x = 3G/20$ $\quad y = 10p_2/G$

for $x = 5G/20$ $\quad y = 10p_3/G$

. . . . . .

for $x = 19G/20$ $\quad y = 10p_{10}/G$

From these figures it is possible to construct a graph showing the form and variation of y with x. From the graph the premiums to be paid may be calculated after the values of A and U have been fixed by agreement. Thereafter adjustments would have to be made in the light of the considerations mentioned previously, it being assumed that the conditions will remain the same during the year.

In Switzerland, one of the foremost countries in dealing with insurance against all calamities caused by the forces of Nature, earthquake insurance is only undertaken by the Canton of Zurich, since the Swiss Re-insurance Union has advised against taking such risks on the grounds that it is impossible completely to predetermine the effects of an earthquake shock.

The "Fonds suisse" is, however, available in cases where insurance is impossible, and this now amounts approximately to two million francs. In New Zealand some earthquake insurance is undertaken by private companies, but the liability of these companies for payments under the Workers' Compensation for Accidents Act has been limited by the Government to £50,000 in a single earthquake or a series of earthquakes lasting seven days. In Great Britain certain companies undertake such insuran on request, but information is unavailable excep from the companies concerned, there being apparent no clearing house for such information. In tl United States, earthquake insurance is underwritt mostly by the mutual fire insurance compani which state that the premiums need not be high due attention is paid to earthquake-proof design in tl buildings concerned.

CRYSTALLO-CHEMICAL ANALYSIS

THE BARKER INDEX AT OXFORD

By Dr. M. W. Porter and R. C. Spiller, Department of Mineralogy, Oxford

EVERY chemist is familiar with the well-developed crystals bounded by plane faces which are formed by chemical substances. That the angles between these faces are characteristic of the substance and can be measured accurately by the reflecting goniometer is also common knowledge.

Clearly it would be of advantage to the chemist were he able to make practical use of these characteristic angles for purposes of identification, as an alternative to the ordinary method of analysis. Only a very small amount of material would be required, for a crystal of the size of one cubic millimetre, or even less, can be accurately measured. Moreover, when the measurement is completed, the crystal remains intact. If an index were made which included all measured substances, arranged in the numerical order of their measured angles, any substance could be identified by measuring a crystal of it and seeking in the index the angular values obtained.

Why has the chemist hitherto been unable to make use of this method of identification?

The difficulty arises from the multiplicity of angles which can be measured on any given crystal and from the lack of guidance in the choice of the angles which are to be used as the basis of the index. It is clear that what is wanted is a set of rules which will ensure that two independent workers who have measured crystals of the same substance will choose, as characteristic of that substance, the same set of angles, by which it can be classified.

The number of chemical substances that have been measured considerably exceeds eight thousand, and the measurements of some seven thousand of these have been collected in the five large volumes of Groth's "Chemische Krystallographie", where they are arranged according to *chemical composition*. During the past thirty years, crystallographers have attempted to put this valuable material into such a form that it might be rapidly and successfully used in the identification of chemical substances. First among those to make such an attempt was Fedorov, the great Russian crystallographer. He devised a method of classification based on his theory of crystal structure and, with the help of his pupils, he produced his great index, "Das Krystallreich", which was published in 1920. It contained a list of all the crystals then measured, and by means of this index any of the substances could be identified by the measurement of its angles. The method employed in this remarkable work was, however, complicated, and the calculations required were lengthy and laborious.

The late Dr. T. V. Barker, of Oxford, who w Fedorov's pupil and enthusiastic collaborator, h hoped to make this method of practical use, but l gradually came to the conclusion that it was ir possible to do so. After many years he devised simpler method based, not as Fedorov's was, up theories of crystal structure, but purely on ge metrical form. His book "Systematic Crystal graphy" (Thomas Murby, London, 1930) describes set of simple rules based on what he termed tl "principle of simplest indices" (*op. cit.*, p. 2), whi he proposed to make the foundation for a practic index of crystals. In this index, under each cryst system, a certain angle, chosen by these rules f each substance as the main classification angle, w to be incorporated in order of increasing magnitud The rules ensured that no ambiguity could ar in the choice of the classification angles. Owi to pressure of other work, Dr. Barker published tl short treatise "Systematic Crystallography" inste of a much larger and more ambitious work, tl uncompleted manuscript of which is in the Universi Museum at Oxford. He hoped to begin work on t index in May 1931, but in April of the same ye he was taken ill and died.

The possibility of compiling the Barker Ind after the untimely death of its originator, and witho his direction, was immediately discussed at Oxfo by a number of crystallographers who were intereste and they decided to try out the method independentl At the end of a year, they unanimously conclud that the method was simple and workable. It w decided to proceed with the preparation of the Ind and, with the kind permission of Prof. H. L. Bowma to make its headquarters in the Mineralogical Depa ment of the University Museum at Oxford.

In the initial stages of the work, certain unforese difficulties arose the solution of which involved tir and labour. The first of these was that, in order cover certain cases, it was found necessary to ma minor modifications and additions in the rules draft by Dr. Barker. The second difficulty was that co siderable delay has been, and will continue to l caused by the misprints and errors of computati found in the original descriptions. These have in cases to be cleared up before the classification ang can be found. In order to guard against simil errors in the Barker Index itself, every calculati is being made independently by two workers a checked by a third before the results are typed or card and filed in a card index.

When some years had been spent in the compila- n of the Index, it was felt that it was sufficiently r advanced to offer material for a searching test its usefulness in the actual identification of com- unds. Such tests had been carried out successfully Dr. Barker and were described in "Systematic ystallography" (pp. 24–27), but his great familiarity th the work and the fact that the material available that time was limited led us to believe that other trial of the method would be of practical lue.

It was decided to carry this out in two of the less nple crystal systems, the orthorhombic and mono- nic, and a list of some 1,230 substances which were ady for the Index was sent to Prof. G. M. Bennett, ofessor of chemistry, King's College, London, who d kindly offered to collaborate in such a test. From is list Prof. Bennett selected sixteen substances ich he sent, numbered, but unnamed, to us at ford. Fifteen of the sixteen were successfully entified. The measurement of the remaining one s not possible as the faces were not sufficiently od to give even fair reflections on the goniometer. e list of substances is given below, and it will be n that many of them have a complicated chemical mposition, and would be difficult to identify by her methods, especially if, as was the case, only e or two small crystals were available for exam- ation. The time taken to identify each compound ried from thirty minutes for the easier crystals to r hours for the most difficult.

T OF COMPOUNDS IDENTIFIED BY MEANS OF THE BARKER INDEX.

Ethyl-2 : 4-dinitrophenyl-aniline. (Groth, 5, 53.)
Methylanilide of benzene sulphonic acid. (Groth, 5, 78.)
Benzene-azo-β-naphthyl benzoate. (Groth, 5, 290.)
Tribenzylamine. (Groth, 5, 323.)
Phenyl benzoate. (Groth, 5, 134.)
1-Phenyl-3-methyl-4-benzylidene-pyrazolone. (Groth, 5, 587.)
Methylanilide of p. toluene sulphonic acid. (Groth, 5, 84.)
Sodium nitroprusside (dihydrate). (Groth, 1, 432.)
Potassium sulphate. (Groth, 2, 337.)
Sulphur. (Groth, 1, 26.)
. . . . . . (unmeasurable).
Ammonium sulphate. (Groth, 2, 344.)
Eugenol benzoate. (Groth, 5, 189.)
Potassium nitrate. (Groth, 2, 74.)
Potassium dihydrogen orthophosphate. (Groth, 2, 795.)
Topaz. (Groth, 2, 202.)

The procedure adopted in these identifications, ich can only be outlined here, was as follows: e crystal (or in some cases two or three crystals) s measured on a two-circle reflecting goniometer. gnomonic or stereographic projection was made m these measurements and the crystal system entified so far as possible from the projection and ecked (if necessary) by the optics. The selection the classification angles was made according to the rker rules. The Index was then consulted under appropriate crystal system for the main classifica- n angle. Generally, a number of angles within limits of the error of measurement offered them- ves. The remaining classification angles were then npared and, when a set which agreed as a whole th those measured was found, the identification s established. When the classification angles licated a member of an isomorphous group, a ther test of a simple nature had to be made. It s recommended by Dr. Barker that such a test uld be made in all cases as a check on the identifi- ion. The test may be a simple chemical one, the ermination of the density, the observation of the colour or cleavage, or the examination of some of the optical properties.

No doubt the question will be asked, what happens if the classification angles are not to be found in the Index? This may happen owing to the fact that the faces of a crystal may vary in different circumstances of crystallization. New faces may appear and old faces may be suppressed. Certain new combinations of faces may give rise to classification angles not to be found in the Index. Actual cases of this sort occurred among the compounds given above and were successfully dealt with as follows: By the graphical insertion into the projection of one or two faces not observed, or the suppression of one or two of the faces present, a new set of classification angles was obtained. These were measured graphically in order to save time and then searched for in the Index, with successful results. Although the difficulty arising from the variability of faces, or of combinations of faces, has been brought forward as a disadvantage of the Barker method (see A. K. Boldyrew und W. W. Doliwo-Dobrowolsky, "Ueber die Bestimmungs-tabellen für Kristalle", *Z. Kristall.*, (A) 93, 321–367; 1936) in actual practice it has not been found to be serious. Nor do the many hundreds of cases of different combinations of faces already recorded give rise to a great number of additional entries in the Index. In working through some 1,800 monoclinic and orthorhombic substances, we have found that about 2,300 entries are required. Donnay and Mélon (see Tables for Tetragonal Substances, Johns Hopkins University, Studies in Geology, No. 11, p. 328; Oct. 1934) in their tables for the tetragonal system found that 456 substances require 582 entries.

A further example of the value of the Barker method may be mentioned. With the help of it, F. A. Bannister and M. H. Hey were able to identify some crystals found in oceanic bottom samples from the Weddell Sea and brought back by the Scotia Expedition (Discovery Reports, 13, 60–69, Cambridge, 1936). The crystals varied in size from 0·2 mm. × 0·1 mm. to 0·3 mm. × 0·15 mm., and several of these were successfully measured and the Barker classification angle determined. The tetragonal symmetry of the crystals was confirmed by their optics and by a Laue photograph. The authors identified the salt as hydrated calcium oxalate from a table of tetragonal substances compiled (independently of the tables by Donnay and Mélon) by Dr. Hey on Dr. Barker's method. Identification in the ordinary way, by means of chemical analysis, was in this case out of the question.

The above identifications give practical evidence of the usefulness of the Barker method, and encourage the belief that when once the Index is complete it will be of great service to chemist and crystallographer alike. Its compilation has now made considerable progress, but new collaborators would be welcomed as the work is necessarily slow. Practical help in the compilation of the Index has been given by Mrs. Barker, P. Terpstra, J. H. Haan, P. Stienstra, J. Mélon, J. D. H. Donnay, M. H. Hey, C. Judson and T. W. J. Taylor.

In conclusion, it may be pointed out that, in the descriptions of new substances to be made in the future, a minimum of calculation will be required if the Barker rules are applied, and the lengthy tables of angles frequently met with in crystallographic descriptions will be unnecessary.

CONTROL OF HEALTH SERVICES

A BROADSHEET, "The Control of Health Services" issued by P E P (Political and Economic Planning) emphasizes the need for an administrative reorganization of the local public health services, and outlines various proposals which have been made with this object. From an administrative standpoint, public health services are divided into those directly administered by the central government departments, those controlled by local authorities under such supervision and the National Health Insurance Scheme. The central department primarily responsible for the public health services in England is the Ministry of Health, but the supervision of the school medical service is delegated to the Board of Education. The Board of Control, which is the supervising body of the services for mental patients and mental defectives, is responsible to Parliament through the Minister of Health, as is the General Register Office dealing with population statistics. Most of the Minister's powers over public health services in Wales are exercised through the Welsh Board of Health, while in Scotland the Department of Health for Scotland performs much the same functions as the Ministry of Health but controls the medical inspection of school children. The Medical Research Council is under a Committee of the Privy Council, while the Factory Act, including its medical provisions, is administered by the Home Office. The National Health Insurance Joint Committee co-ordinates the work of the Ministry of Health, the Department of Health for Scotland, the Welsh Board of Health and the Ministry of Labour for Northern Ireland in connexion with National Health Insurance.

Eighty-three county boroughs in England and Wales exercise all statutory health functions allocated to local government, but outside their territory these are distributed between 62 county councils, including the London County Council, 306 municipal boroughs, 575 urban districts, 476 rural districts, 28 metropolitan boroughs and the Corporation of the City of London. The 24 large Scottish burghs are virtually independent health authorities but except in Aberdeen, Dundee, Edinburgh and Glasgow are not concerned with the school medical services, wh the 171 small burghs have fewer public Heal functions in their own right than the English distr councils.

Administrative boundaries are already hinderi developments which are possible through mode transport in centralization of equipment, and aer defence is making regional planning of health servi more urgent. The criticism in the report on t Anti-Tuberculosis Service in Wales and Monmout shire could probably be applied to many areas England. Financial stringency is not the only ca of failure to deal with overcrowding; failure of t counties to put pressure on inefficient district counc and to carry through a review of their areas, nepotis prejudice, individualism and a refusal to spe money on communal services are contributory caus The Committee on the Scottish Health Services 1936 advocated that the Department of Heal should be empowered to call on local authorities submit schemes for the provision and maintenan of certain services for the areas of two or mo authorities and similar proposals were made in t minority report of the Royal Commission on Lo Government in the Tyneside Area in 1937 as alternative to an even more radical proposal of t majority report for administration of specif health services by a regional authority.

Practically all these schemes, like that of t British Medical Association, "A General Medi Service for the Nation", propose an administrati division between the environmental and the perso health services, the former being administered local units and the latter by regional authorities o a wide area. The British Medical Association sche proposed that councils with a population of less th 75,000 in rural and 100,000 in urban areas shou leave all their public health functions to a system complete and comprehensive local public heal administration units. The plans of the Ministry Health to meet an emergency as revealed in t House of Commons may ultimately lead to radi changes in the organization of the health services.

MACROMOLECULES

IN a lecture to the Freiburger wissenschaftliche Gesellschaft (published by Hans Speyer Verlag Hans Ferdinand Schulz, Freiburg im Breisgau), Prof. H. Staudinger reviews the nature and importance of macromolecules, which play such an important part in the chemistry of living tissues. These compounds possess many unexpected properties which cannot be foreseen from a study of simpler substances.

A macromolecule is defined as one built up of not less than a thousand atoms bound together by primary valencies. At present no upper limit is known to the size of the molecule, but it is possible to group them into threads, plates and spheres. The simplest are high polymers derived from simple unsaturated compounds, for example, vinyl chloride polymerizes to a product in which three thousand simple molecules are combined by co-valencies a which is used for synthetic leather, tubing, etc. this case the product is a complex mixture which c be partly resolved by fractionation into what called *polymerhomologues*. Svedberg has shown th the molecules of many proteins are uniform b native cellulose can be partly depolymerized in lower products with varying degrees of polymeri tion. Thus a polymerhomologous series of cellulo exists and the same holds also for starch, glycog caoutchouc and balata.

A method has been found of studying changes physical properties of the products and of th solutions with change in degree of polymerizati Both homopolar and heteropolar combinations known. Hydrocarbons like polystyrols may form s with organic solvents but not with water, while the introduction of hydroxyl groups may reverse this effect. Again, the introduction of polar groups may result in hydrosol formation. By the polymerization of acrylic acid, it is possible to build up a complete polymerhomologous series with degrees of polymerization ranging from 10 to 2,000. These acids and their salts give osmotic pressures which are about one fifth of the theoretical values, and polyvalent anions may exert a similar buffering effect on the osmotic pressures of cations. The behaviour of albumens is particularly complicated, since both acid and basic radicals are present. The polyacrylic acids have served as a model in unravelling these complexities. The physical properties of linear or thread molecules depend on molecular length. It is convenient to group them into hemicolloids with length from 50 A. to 250 A., mesocolloids (250–2,500 A.) and eucolloids (above 2,500 A.) of which only the last-named group possesses typical macromolecular properties such as toughness, fibrous structure and the power of swelling. The viscosities of heteropolar thread molecules are complicated by swarming of the fibre-ions, which is affected by the presence of salts and acids.

Since macromolecules have the dimensions of colloid particles, any solutions that are formed are colloidal and may be termed macrocolloidal to distinguish them from the molecular colloids or micelles of soaps and dyes, which are very much less stable, since they do not involve principal valencies. In some cases macromolecules are formed by true condensation, for example, through loss of water. It is necessary to be able to distinguish between macromolecules and micelles. Particle size in homopolar compounds can be determined from osmotic pressure and with the help of the ultracentrifuge. The study of acetylated products is of great importance, for if the degree of polymerization is unaltered by acetylation the original compound must have been macromolecular since micelles could not withstand such drastic treatment. Unfortunately, this very simple principle is difficult in application since by-reactions may have a far-reaching effect.

Chemical investigation is rendered difficult by the fact that the greater the size of the macromolecule the smaller is the proportion of active reagent (water, oxygen, etc.) needed to bring about chemical change. Native caoutchouc contains thread molecules with a degree of polymerization of two to three thousand and swells greatly in water. On exposure to air the threads become linked at few points only by oxygen bridges so that an insoluble product results with limited swelling power, but the amount of oxygen absorbed is too small to determine. Nitrogen has no such action. Again, synthetic polystyrol threads can be linked at long intervals by using a minute amount of divinylbenzene so that a network is obtained which can be solvated but not dissolved. In some similar fashion, albumens can pass from a soluble form with unlimited swelling power to an insoluble form with limited swelling. Again, minute chemical changes such as methylation of terminal groups alone of a very long chain may influence chemical character; thus the dimethylether of polyoxymethylene is stable to sodium hydroxide. These facts are of great importance in the study of hormones and vitamins, which may be regarded not as mere catalysts but as reagents capable of reacting in minute quantities on macromolecules to produce far reaching effects.

SCIENCE NEWS A CENTURY AGO

The August Meteors seen at Breslau

ON August 14, 1839, the German astronomer Boguslawski wrote an account of his observations at Breslau of the August meteors, popularly known as "the tears of St. Lawrence"; the account being published in the Prussian State Gazette. "The sky," he said, "has been again particularly propitious for observing another fall of stars. On many days and nights preceding the 10th the heavens have been so covered that we could not observe when the uncommonly frequent fall of stars commenced. On Aug. 10, however, our hopes of seeing the phenomena increased owing to the clearness of the weather. . . . It was not, however, sufficient to count the numbers that fell; it was desirable also to measure the time of their appearance, and of the continuance of their fall, according to Franzmann's instrument, which beats thirds of seconds, and moreover to ascertain their relative height and apparent course in the heavens and all these observations could commence only at 26 minutes past 9 when all the observers, 15 in number, were assembled, occupying six windows of the observatory. Four gentlemen took care to observe and register the times of each appearance, according to two clocks. Till 14 minutes past 3, when dawn put a stop to the observations, they noticed 1008 falling stars, not including numbers which must have been overlooked because the numbers of observers was insufficient". Other meteors were seen on August 11 and 12 and "therefore," wrote Boguslawski, "the annual periodical return of an uncommon fall of stars towards the 10th of August is once more confirmed".

Steam Applied to Land Drainage

ON August 17, 1839, the *Mechanic and Chemist* said: "This drainage of land by steam power has been extensively adopted in the fens of Lincolnshire, Cambridgeshire, and Bedfordshire and with immense advantage. An engine of forty horse power, and scoop wheel for draining, and requisite buildings, costs about £4,000, and is capable of draining about 4,000 acres of land. In many places in the fens, land has been purchased at from £10 to £12 per acre, which has been so improved by drainage as to be worth £60 or £70 per acre". One of the largest districts drained was Deeping Fen near Spalding containing 25,000 acres, where there were pumping engines of 80 horse-power and 60 horse-power. Littleport Fen, near Ely of about 28,000 was drained by two engines whereas formerly there were 75 wind-driven pumps. Soham Mere, near Cambridge, forming a lake of 1,600 acres was drained by a 40 horse-power engine.

UNIVERSITY EVENTS

CAMBRIDGE.—J. C. Colbeck has been elected John Lucas Walker student.

A. F. Huxley, of Trinity College, has been elected to the Michael Foster studentship in physiology.

Dr. K. C. Dixon, of King's College, has been awarded the E. G. Fearnsides scholarship.

OXFORD.—Dr. L. A. Woodward, Lincoln College, has been appointed fellow and tutor of Jesus College in chemistry in succession to the late H. J. George.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

HEAD OF THE CHEMISTRY DEPARTMENT and a LECTURER IN ELECTRICAL ENGINEERING at the Burnley Municipal College—The Director of Education, Education Offices, Burnley (August 15).

GRADUATE LECTURER IN MECHANICAL ENGINEERING at the Coventry Technical College—The Director of Education, Council House, Coventry (August 16).

LABORATORY ASSISTANT (Male)—The Commandant, Experimental Station, Porton, near Salisbury (August 18).

HEAD OF THE DEPARTMENT OF ELECTRICAL ENGINEERING at the Liverpool Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (August 23).

PROFESSOR OF VETERINARY SURGERY, OBSTETRICS AND ANIMAL HUSBANDRY at the Veterinary College, Ballsbridge, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (August 23)

PART-TIME DEMONSTRATOR IN BOTANY—The Secretary, Kings College, Strand, W.C.2 (August 26).

LECTURER IN CIVIL ENGINEERING at the Brighton Technical College—The Education Officer, 54 Old Steine, Brighton (August 26).

UNIVERSITY LECTURER IN PHYSICS—The Secretary of the Appointments Committee of the Faculty of Physics and Chemistry, Cavendish Laboratory, Cambridge (August 31).

RESEARCH ASSISTANT in the Department of Coal Gas and Fuel Industries with Metallurgy—The Registrar, University, Leeds 2 (September 1).

INSTRUCTRESS IN RURAL DOMESTIC SCIENCE at the East Anglian Institute of Agriculture, Chelmsford—The Clerk of the County Council, County Hall, Chelmsford (September 1).

RESEARCH OFFICER in the Pathological Division of the Tea Research Institute of Ceylon—The Secretary, Ceylon Association in London, 11 Idol Lane, E.C.3 (September 9)

PROFESSOR OF ELECTRICAL ENGINEERING in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2 (September 15).

LECTURER in the Physiological Department—The Secretary, University, Birmingham 3 (September 16).

BACTERIOLOGIST—The Secretary, Royal College of Physicians, Edinburgh 2 (September 20).
